# MULTIGRID METHODS FOR PROBLEMS WITH A <br> SMALL PARAMETER IN THE HIGHEST DERIVATIVE 

## P.W. Hemker

## 1. INTRODUCTION

Much progress has been made recently in developing multigrid (MG-) methods to solve the systems of equations that arise from discretization of truly elliptic PDEs. Often the emphasis lies upon the search for the most efficient variant. However, for the MG-methods to be generally applied, it is important that the methods are not only efficient, but also that they do not fail or do not need particular adaptation for special cases of the general elliptic equation. Therefore, in this paper, we consider the elliptic equation when it degenerates because a coefficient in the highest derivative tends to zero and we study the behaviour of some MG-methods under these circumstances. Related problems are studied in $[2,4,5,12,15,22]$.

Our main objective is the development of methods for the general linear $2^{\text {nd }}$ order elliptic PDE with variable coefficients

$$
\begin{equation*}
\mathrm{Lu} \equiv-\nabla(\overline{\bar{\varepsilon}} \nabla \mathrm{u})+\overline{\mathrm{b}} \nabla \mathrm{u}+\mathrm{cu}=\mathrm{f} \text { on } \Omega, \tag{1.1}
\end{equation*}
$$

$$
\begin{array}{ll}
\mathrm{u} & =\mathrm{g} \text { on } \Gamma_{D}, \\
\overline{\mathrm{n}} \overline{\bar{\varepsilon}} \nabla \mathrm{u}=\mathrm{h} \text { on } \Gamma_{\mathrm{N}}, & \Omega \subset \mathbb{R}^{2} \text { bounded, } \\
\Gamma_{\mathrm{N}} \cup \Gamma_{\mathrm{D}}=\delta \Omega .
\end{array}
$$

Here $\nabla=(\partial / \partial x, \partial / \partial y)$, and $\overline{\bar{\varepsilon}}$ is symmetric positive definite $2 \times 2$ matrix. The coefficients $\bar{b}$ and $c$ and the data $f, g$ and $h$ are real functions on $\Omega$ or $\partial \Omega$.

In particular our interest goes to cases where general methods easily fail: (i) $\overline{\bar{\varepsilon}}$ has one small eigenvalue and (ii) $\overline{\bar{\varepsilon}}$ has two small eigenvalues w.r.t. $|\overline{\mathrm{b}} \mathrm{h}|$, where $h$ is a characteristic length (e.g. the meshsize). To investigate these cases in detail we consider two constant coefficient model problems. The first is the anisotropic diffusion equation:

$$
\begin{equation*}
L_{\varepsilon} u \equiv-\left(\varepsilon c^{2}+s^{2}\right) u_{x x}-2(\varepsilon-1) s c u_{x y}-\left(\varepsilon s^{2}+c^{2}\right) u_{y y}=f, \tag{1.2}
\end{equation*}
$$

with $c=\cos (\alpha)$ and $s=\sin (\alpha)$. This equation is obtained from $-\varepsilon u_{x x}-u_{y y}=f$ by rotation with an angle $\alpha$. The eigenvalues of $\overline{\bar{\varepsilon}}$ are 1 and $\varepsilon$. The second problem is the convection-diffusion equation:

$$
\begin{equation*}
L_{\varepsilon} u \equiv-\varepsilon\left(_{u_{x x}}+u_{y y}\right)+c u_{x}+s u_{y}=f \tag{1.3}
\end{equation*}
$$

Here $\varepsilon$ is a scalar coefficient and the convection direction is given by $\alpha$.
We must keep in mind that in applications $\bar{b}$ and $c$ are variable coefficients and the direction of the anisotropy or the convection is a priori unknown. Therefore we
keep $\alpha$ as a parameter and we disregard the possibility of alignement of coordinate axes to the special direction in the equation.

Solutions of (1.2) and (1.3) may show layers, i.e. regions in which the solution varies rapidly. For (1.2) these layers may appear along lines in the direction of the strong diffusion. For (1.3) they may appear along the subcharacteristics or at the outflow boundary.

For the discretization of (1.1) we use methods of the finite element (FE) type. We assume that $\Omega$ can be covered by a triangularization $T_{h}$ in a regular rectangular grid

and we use spaces of trialfunctions $S^{h}$ and testfunctions $V^{h}$, such that the support of a basisfunction $\phi_{i}$ (or $\psi_{i}$ ) in $S^{h}$ (or $V^{h}$ ) consists of only the triangles that are connected with the nodal point $x_{i}$.

For simple functions $\phi_{i}$ and $\psi_{i}$ these discretizations

$$
\begin{equation*}
L_{h} u_{h}=f_{h} \tag{1.4}
\end{equation*}
$$

yield coefficient matrices $L_{h}$ with a regular 7-diagonal structure. The standard (FEM) method is with both $\phi_{i}$ and $\psi_{i}$ continuous piecewise linear. The 7-point discretizations are the simplest ones by which also a cross-term derivative $u_{x y}$ can be represented.

## 2. THE MULTIGRID ALGORITHM

The multigrid method considered here is an iterative process for the solution of (1.4). It makes use of a sequence of discretizations on grids coarser than used for $L_{h} u_{h}=f_{h}$. Each next coarser grid has a doubled meshsize and is obtained by leaving out each second meshline.

In the multigrid method (MGM) each iteration cycle consists of:
1.) p (pre-) relaxation sweeps;
2.) a coarse grid correction;
3.) q (post-) relaxation sweeps.

The coarse grid correction (GGC) consists of:
a) the computation of the current residual, $r_{h}:=f_{h}-L_{h} u_{h}$;
b) the restriction of the residual to the next coarser grid, $r_{H}:=\bar{R}_{H h} r_{h}$;
c) the computation of $\tilde{c}_{H}$, the approximate solution of the correction equation on coarser grid:

$$
\begin{equation*}
L_{H} c_{H}=r_{H}, \tag{2.1}
\end{equation*}
$$

by application of $s$ MGM iteration cycles to this equation;
d) an update of the current solution $u_{h}$ by addition of the prolongated (interpolated) correction

$$
u_{h}:=u_{h}+p_{h H} \tilde{c}_{H} .
$$

By the recursive structure of this algorithm a coarsest grid exists on which the correction equation (2.1) has to be solved by another method (at choice). The coarse grid discrete operators $L_{H}$ can be contained either by discretization, analogous to $L_{h}$, or by the construction of the GaZerkin approximation

$$
\begin{equation*}
L_{H}=\bar{R}_{H h} L_{h} P_{h H} \tag{2.2}
\end{equation*}
$$

We see that, beside the choice of the operator $L_{H}$, for a CGC we have to choose operators for the restriction ( $\bar{R}_{\mathrm{Hh}}$ ) and prolongation ( $\mathrm{P}_{\mathrm{hH}}$ ). These operators are discussed in section 3 .

If (2.1) is solved exactly, no coarser discretizations than $L_{H}$ are involved, and the algorithm is a two-grid method (TGM). Its CGC is described by

$$
\begin{equation*}
u_{h}:=u_{h}+P_{h H} L_{H}^{-1} \bar{R}_{H h}\left(f_{h}-L_{h} u_{h}\right) \tag{2.3}
\end{equation*}
$$

It can be shown [8] that under suitable conditions, for $s$ large enough (roughly $s \geq 2$ ), the convergence behaviour of the MGM is almost the same as of the TGM. In practice, also $s=1$ is often a good choice.

Most essential for the efficiency of the MGM is the choice of the relaxation method. Methods that are often used in this context are Point Gauss-Seidel relaxations (scanning the points in some order e.g. red-black or various lexicographical orderings), Line Gauss-Seidel relaxations (with different possible line-orderings, e.g. zebra or lexicographical [19]). Other relaxation methods are based on incomplete decompositions of the coefficient matrix, viz. Incomplete LU-decomposition (ILU-) relaxation or Incomplete Line-LU- (ILLU-) relaxation. All these relaxation methods are of the form

$$
\begin{equation*}
\tilde{L}_{h} u_{h}^{(i+1)}=\tilde{L}_{h} u_{h}^{(i)}-L_{h} u_{h}^{(i)}+f_{h} \tag{2.4}
\end{equation*}
$$

where $\tilde{L}_{h}$ is an approximation to $L_{h}$.
For ILU relaxation, in each sweep a linear system is solved of the form

$$
L U u_{h}^{(i+1)}=f_{h}+R u_{h}^{(i)}
$$

where $\tilde{L}_{h}=L U=L_{h}-R$ is an approximate Crout-decomposition of $L_{h}$, with $L$ and $U$ lower and upper triangular matrices with the same sparsity structure as $L_{h}[17,20]$.

For ILLU relaxation $[15,16]$ in each sweep $u_{h}^{(i+1)}$ is solved from a system

$$
\begin{equation*}
(L+\bar{D}) \bar{D}^{-1}(\bar{D}+U)\left(u_{h}^{(i+1)}-u_{h}^{(i)}\right)=f_{h}-L_{h} u_{h}^{(i)} \tag{2.5}
\end{equation*}
$$

The matrices $L, \bar{D}$ and $U$ are obtained from the coefficient matrix $L_{h}$, written in block-tridiagonal form as

The block-diagonal matrix $\overline{\mathrm{D}}$, with the same sparsity pattern as D , is computed recursively from

$$
\left\{\begin{array}{l}
\bar{D}_{1}=D_{1},  \tag{2.6}\\
\bar{D}_{j}=D_{j}-\underline{\text { tridiag }}\left(L_{j} \bar{D}_{j-1}^{-1} U_{j-1}\right), \quad j=2,3, \ldots, n,
\end{array}\right.
$$

where tridiag is the operator which selects the tridiagonal submatrix from a dense matrix.

## 3. NESTED DISCRETIZATIONS

The relation between the discretizations on the different grids in a MGM can be considered analogous to the relation between the continuous and a discrete problem. For discretization of an equation $L u=f,(L: X \rightarrow Y, X$ and $Y$ Banach spaces), we relate to it the discrete equation $L_{h} u_{h}=f_{h},\left(L_{h}: X_{h} \rightarrow Y_{h}\right)$. The relation between the two equations is made by the prolongation $P_{h}: X_{h} \rightarrow X$ (a linear injection) and the restrictions $R_{h}: X \rightarrow X_{h}$ and $\bar{R}_{h}: Y \rightarrow Y_{h}$ (linear surjections).

In the same way coarser discretizations $L_{H}{ }_{H}{ }_{H}=f_{H}$ are related to finer $L_{h} u_{h}=f_{h}$ by a prolongation $P_{h H}: X_{H} \rightarrow X_{h}$ (linear injection), and restrictions $R_{H h}: X_{h} \rightarrow X_{H}$ and $\bar{R}_{H h}: Y_{h} \rightarrow Y_{H}$ (linear surjections). The coarse grid Galerkin approximation (2.2) is the analogue of the Galerkin discretization $L_{h}=\bar{R}_{h} L P_{h}$. A sequence of nested discretizations of acontinuous equation $L u=f$ is obtained by selecting prolongations and restrictions such that

$$
\begin{equation*}
P_{H}=P_{h} P_{h H}, R_{H}=R_{H h} R_{h}, \bar{R}_{H}=\bar{R}_{H h} \bar{R}_{h} . \tag{3.1}
\end{equation*}
$$

In the standard FE discretization (sect. 1) the prolongation $P_{h}: X_{h} \rightarrow X$ is defined by linear interpolation over the triangles of $T_{h} ; R_{h}: X \rightarrow X_{h}$ is defined by injection (i.e. restriction of the function values to nodal points) and $\bar{R}_{h}$ is defined by weighting by the continuous piecewise linear basis-functions $\phi_{i}^{h} \in V^{h}$ :

$$
\begin{equation*}
\left(\bar{R}_{h} f\right)_{i} \equiv\left(f_{h}\right)_{i} \equiv \int f(x) \phi_{i}^{h}(x) d \Omega \tag{3.2}
\end{equation*}
$$

The FE discretization corresponds to the Galerkin discretization $L_{h}=\bar{R}_{h} L P_{h}$.
To obtain a sequence of nested discretizations related with the FE discretization, we use a corresponding $P_{h H}$ and $\bar{R}_{\mathrm{Hh}}$. The prolongation $\mathrm{P}_{\mathrm{hH}}$ should satisfy (3.1) with linear interpolation for $P_{h}$ and $P_{H}$. Hence,

$$
P_{H} u_{H}=\sum_{j} u_{j}^{H} \phi_{j}^{H}=\sum_{j, i} u_{j}^{H}{ }_{j}^{H} j_{i} \phi_{i}^{h}=\sum_{i}\left(\sum_{j} r_{j i} u_{j}^{H}\right) \phi_{i}^{h}=P_{h} P_{h H} u_{h} .
$$

Therefore, $\mathrm{P}_{\mathrm{hH}}$ is given by the prolongation molecule

$$
P_{h H}^{*}=\left(r_{j i}\right)=\left[\begin{array}{ccc} 
& \frac{1}{2} & \frac{1}{2}  \tag{3.3}\\
\frac{1}{2} & 1 & \frac{1}{2} \\
\frac{1}{2} & \frac{1}{2} &
\end{array}\right]
$$

For $\overline{\mathrm{R}}_{\mathrm{Hh}}$ we have

$$
\left(\bar{R}_{H h} f_{h}\right)_{i}=\left(f_{H}\right)_{i}=\int f(x) \phi_{i}^{H}(x) d \Omega=\int f \sum_{j} r_{i j} \phi_{j}^{h} d \Omega=\sum_{j} r_{i j}\left(f_{h}\right)_{j} ;
$$

the restriction molecule $\overline{\mathrm{R}}_{\mathrm{Hh}}^{*}$ of $\overline{\mathrm{R}}_{\mathrm{Hh}}$ is also given by (3.3). In this case $\overline{\mathrm{R}}_{\mathrm{Hh}}=\left(\mathrm{P}_{\mathrm{hH}}\right)^{\mathrm{T}}$. These $P_{h H}$ and $\bar{R}_{\mathrm{Hh}}$ are the same 7-point prolongation and restriction as introduced in [20,21]. For points near the boundary obvious modifications of the molecules have to be made.

With the $P_{h H}$ and $\bar{R}_{H h}$ given by (3.3), the FE discretization on the different levels form a nested sequence and $L_{H}$ can be computed from $L_{h}$ by (2.2):

$$
\begin{equation*}
L_{H}=\bar{R}_{H} L_{H}=\bar{R}_{H h} \bar{R}_{h} L_{h} P_{h} P_{h H}=\bar{R}_{H h} L_{h} P_{h H} . \tag{3.4}
\end{equation*}
$$

Starting with the discretization $L_{h}$ on $N$ meshpoints, and using (3.3) for $\bar{R}_{H h}$ and $P_{h H}$, it takes less than 29 N additions and $7 / 3 \mathrm{~N}$ multiplications to compute the discrete operators on all coarser grids.

Application of FEM to the constant coefficient equation (1.1) on an equidistant regular $T_{h}$ yields the 7 -point difference molecules

$$
\begin{align*}
& -h^{2}\left(\frac{\partial}{\partial x}\right)^{2} \sim\left[\begin{array}{ccc}
-1 & 0 \\
0 & 2 & 0 \\
0 & -1
\end{array}\right]=A_{11}^{*},-h^{2}\left(\frac{\partial}{\partial y}\right)^{2} \sim\left[\begin{array}{ccc} 
& 0 & 0 \\
-1 & 2 & -1 \\
0 & 0 &
\end{array}\right]=A_{22}^{*}  \tag{3.5}\\
& -2 h^{2}\left(\frac{\partial}{\partial x}\right)\left(\frac{\partial}{\partial y}\right) \sim\left[\begin{array}{ccc}
1 & 1 & -1 \\
-1 & 1 & 1
\end{array}\right]=A_{12}^{*},
\end{align*}
$$

the $2^{\text {nd }}$ order terms; and

$$
6 h\left(\frac{\partial}{\partial x}\right) \sim\left[\begin{array}{ccc} 
& -2 & -1  \tag{3.6}\\
-1 & 0 & 1 \\
1 & 2 &
\end{array}\right]=A_{1}^{*}, \quad 6 h\left(\frac{\partial}{\partial y}\right) \sim\left[\begin{array}{ccc}
-2 & -1 & 1 \\
-1 & 1 & 2
\end{array}\right]=A_{2}^{*},
$$

the $1^{\text {st }}$ order terms; and

$$
12 I \sim\left[\begin{array}{lll} 
& 1 & 1  \tag{3.7}\\
1 & 6 & 1 \\
1 & 1 &
\end{array}\right]=A_{0}^{*} .
$$

the $0^{\text {th }}$ order term.
For each $p$-th order difference molecule $A_{h}^{*}$ in (3.5)-(3.7) we find ( $H=2 h$ )

$$
\begin{equation*}
\overline{\mathrm{R}}_{\mathrm{Hh}}^{*} * \mathrm{~A}_{\mathrm{h}}^{*} * \mathrm{P}_{\mathrm{hH}}^{*}=2^{2-\mathrm{p}_{\mathrm{A}_{2 h}}^{*}} \tag{3.8}
\end{equation*}
$$

where.*.*. denotes the combined application of the prolongation and restriction (i.e.
convolution and contraction of the molecules). This means that the difference molecules (3.5)-(3.7) are all invariant under Galerkin approximation. The factor $2^{2-p}$ takes into account the difference in meshsize on the different levels. A $7^{\text {th }}$ linearly independent 7 -point molecule,

$$
A_{3}^{*}=\left[\begin{array}{ccc}
-1 & 1  \tag{3.9}\\
1 & 0 & -1 \\
-1 & 1 &
\end{array}\right] \sim h^{3}\left(\frac{\partial}{\partial t}\right)\left(\frac{\partial}{\partial y}\right)\left(\frac{\partial}{\partial x}-\frac{\partial}{\partial y}\right)
$$

satisfies (3.8) with $p=3$.
It follows that other than FEM molecules are not invariant under Galerkin approximation with $\overline{\mathrm{R}}_{\mathrm{Hh}}$ and $\mathrm{P}_{\mathrm{hH}}$ given by (3.3). Examples are:

1) the central difference operator

$$
\begin{equation*}
6 h\left(\frac{\partial}{\partial x}\right) \sim A_{1}^{*}+A_{3}^{*} \tag{3.10}
\end{equation*}
$$

2) the upwind difference operator

$$
\begin{equation*}
6 h\left(\frac{\partial}{\partial x}\right) \sim U_{1}^{*}=A_{1}^{*}+A_{3}^{*}+3 A_{11}^{*} \tag{3.11}
\end{equation*}
$$

For any of these discretizations on the finest grid, the repeated use of (2.2) with the $P_{h H}$ and $\bar{R}_{\text {Hh }}$ given by (3.3), yields discretizations on coarser grids that tend to the FE discretization. E.g., for (3.11) $k$ times application of (3.8) yields

$$
\begin{equation*}
\left(R^{*} *\right)^{k}\left(h U_{1}^{*}\right)\left(* P^{*}\right)^{k}=2^{k} h\left[A_{1}^{*}+2^{-2 k} A_{3}^{*}+3 \cdot 2^{-k} A_{11}^{*}\right] \tag{3.12}
\end{equation*}
$$

which tends to $2^{k} h A_{1}^{*}$ as $k$ increases.

## 4. THE ANISOTROPIC DIFFUSION EQUATION

The 7 -point molecule for (1.2) obtained by FEM reads

$$
L_{h, \varepsilon}^{*}=\left[\begin{array}{ccc} 
& s(c-s) & -s c  \tag{4.1}\\
c(s-c) & 2-2 s c & c(s-c) \\
-s c & s(c-s) &
\end{array}\right]+\varepsilon\left[\begin{array}{ccc} 
& -c(s+c) & s c \\
-s(s+c) & 2+2 s c & -s(s+c) \\
s c & -c(s+c) &
\end{array}\right]
$$

To investigate the relaxation methods for (4.1) we use Local Mode Analysis [19], i.e. we consider the discretization on an infinite domain (or on a finite domain with periodic boundary conditions). For the linear constant coefficient (difference) operator $L$ (or $L_{h}$ ) its symbol $\hat{L}(\omega)$ (or $\hat{L}_{h}(\omega)$ ) is introduced by

$$
\mathrm{Lu}_{\omega}=\hat{\mathrm{L}}(\omega) \mathrm{u}_{\omega} \text { or } \quad \mathrm{L}_{\mathrm{h}}{ }_{\omega}=\hat{\mathrm{L}}_{h}(\omega) u_{\omega},
$$

where

$$
\begin{aligned}
& u_{\omega}(x, y)=e^{i\left(\omega_{1} x+\omega_{2} y\right)} \\
& \hat{L}: \mathbb{R}^{2} \rightarrow \mathbb{C} \\
& \hat{L}_{h}: T_{h}^{2} \equiv[-\pi / h, \pi / h]^{2} \rightarrow \mathbb{C}
\end{aligned}
$$

$T_{h}^{2}$ is the domain of all frequencies $\omega$ that are visible on a grid with meshsize $h$. For convenience we use also the notation $\phi=h \omega_{1}, \theta=h \omega_{2}$, and $u_{\omega}=u_{\phi, \theta}$.

For equation (1.2) we find the symbol

$$
\begin{equation*}
h^{2} \hat{L}_{\varepsilon}(\phi, \theta)=(s \phi-c \theta)^{2}+\varepsilon(c \phi+s \theta)^{2} . \tag{4.2}
\end{equation*}
$$

For $\varepsilon>0,(\phi, \theta) \neq(0,0)$ we have $\hat{\mathrm{L}}_{\hat{\xi}}(\omega)>0$, which shows the ellipticity of $\mathrm{L}_{\varepsilon}$. For the reduced case, $\varepsilon=0$, we have

$$
\begin{equation*}
L_{\varepsilon}(\phi, \theta)=0 \text { iff } s \phi=c \theta . \tag{4.3}
\end{equation*}
$$

This problem is not longer elliptic and it has unstable modes $u_{\phi, \theta}$ for $(\phi, \theta)$ satisfying (4.3). For the discretized problem (1.2), we derive from (4.1)

$$
\begin{align*}
\hat{\mathrm{L}}_{\mathrm{h}, \varepsilon}(\phi, \theta) & =[\mathrm{s}+(\mathrm{c}-s) \cos \phi-\mathrm{c} \cos (\phi-\theta)]^{2}+[(\mathrm{c}-\mathrm{s}) \sin \phi-\mathrm{c} \sin (\phi-\theta)]^{2}  \tag{4.4}\\
& +\varepsilon[c-(\mathrm{c}+\mathrm{s}) \cos \phi+s \cos (\phi-\theta)]^{2}+\varepsilon[(\mathrm{c}+\mathrm{s}) \sin \phi-s \sin (\phi-\theta)]^{2} .
\end{align*}
$$

Again $\hat{\mathrm{L}}_{\mathrm{h}, \varepsilon}(\phi, \theta)>0$ for $\varepsilon>0,(\phi, \theta) \neq(0,0)$, but for $\varepsilon=0$ we see

$$
\begin{align*}
& \hat{\mathrm{L}}_{\mathrm{h}, 0}(\phi, \theta)=0 \text { iff (i) } \phi=\theta=0, \\
& \text { or (ii) } \phi=0 \text { and } c=0,  \tag{4.5}\\
& \text { or (iii) } \theta=0 \text { and } s=0, \\
& \text { or (iv) } \phi=\theta \text { and } s=c .
\end{align*}
$$

Except for $\phi=\theta=0$, the discrete operator has unstable modes only if the direction of the strong diffusion is along one of the (three) gridline directions. For all other $\alpha$ we find $L_{L, 0}(\phi, \theta)>0$ for $(\phi, \theta) \neq(0,0)$. If the strong diffusion is not along the gridlines, the discrete scheme is elliptic where the original operator is not. The discretization introduces artificial cross-diffusion.

For $\alpha \neq 0, \pi / 4, \pi / 2$, this extra stability guarantees the existence of a relaxation method for its solution [6] (viz. a properly damped Jacobi relaxation). How to find an efficient relaxation, however, is not immediately clear. This is particularly so because (4.1) does not yield an L-matrix (non-negative off-diagonal elements) for all $\varepsilon$ and $\alpha$, and hence e.g. ILU-relaxation may diverge. The domain is the $\alpha-\varepsilon-p l a n e$ where $L_{h, \varepsilon}$ is an L-matrix is shown in figure 4.1.

Fig. 4.1. The shaded area denotes the domain in the ( $\alpha, \varepsilon$ )-plane where (4.1) yields an L-matrix.
We see that $\alpha=0, \pi / 4, \pi / 2$ play again a special role. Therefore in numerical experiments more angles $\alpha$ have to be considered to obtain an insight in the general behaviour of the smoothing processes. Here, to examine the relaxation methods, we compute the smoothing factor (cf. [19] sect. 7) for various ( $\alpha, \varepsilon$ ), for lexicographical Gauss-Seidel, zebra, ILU and ILLU relaxation. The smoothing factor gives a first
impression of the rate of convergence of a MGM with $p+q=1$.

Table 4.1 Smoothing factors by Local Mode Analysis of lexicographic Point GaussSeidel, zebra, ILU and ILLU relaxation for (4.1).

From table 4.1 we see that Gauss-Seidel relaxation is slow for small $\varepsilon$, zebra smoothing is essentially better. For angles $\pi / 4 \leq \alpha \leq \pi$ the ILU is an excellent smoother, but for $0<\alpha<\pi / 4$ it is unreliable and may diverge. This divergence, found by local mode analysis, appears for modes $u_{\phi, \theta}$ with $(\phi, \theta) \approx(0, \pi)$ if $0<\alpha<\pi / 8$ and for $(\phi, \theta) \approx(-\pi, \pi)$ if $\pi / 8<\alpha<\pi / 4$. The same modes are also found to diverge in real MGM-iterations if a fine enough grid is used. The ILLU relaxation converges rapidly in all cases.

That ILU is a good smoother for $\pi / 4<\alpha<\pi$ for all $\varepsilon$ can be explained by the fact that (4.1) with $\varepsilon=0$ can be decomposed into a product of two molecules corresponding to the LU decomposition. Two of these decompositions are possible

$$
\begin{align*}
{\left[\begin{array}{ccc} 
& s(c-s) & -c s \\
c(s-c) & 2-2 c s & c(s-c) \\
-c s & s(c-s)
\end{array}\right.} & =\left[\begin{array}{ccc} 
& s(c-s) & 0 \\
c(s-c) & (s-c)^{2} & 0 \\
0 & 0
\end{array}\right] *\left[\begin{array}{ccc} 
& 0 & 0 \\
0 & \frac{1}{s} & \frac{c}{s-c} \\
0 & \frac{s-c}{s-c}
\end{array}\right]  \tag{4.6}\\
& =\left[\begin{array}{ccc} 
& s(c-s) & -c s \\
0 & s^{2} & 0 \\
0 & 0 & 0
\end{array}\right] *\left[\begin{array}{ccc}
0 & 0 & 0 \\
-c / s & \frac{c-s}{s}
\end{array}\right] \tag{4.7}
\end{align*}
$$

Decomposition (4.7) has a bounded inverse for $\pi / 4<\alpha<\pi / 2$ and (4.6) for $\pi / 2<\alpha<\pi$. For these ranges of $\alpha$, the corresponding decompositions are also those found by the LU-decomposition algorithm as described in [20,21]. However, neither (4.6) nor (4.7) is found for $0<\alpha<\pi / 4$. For small $\varepsilon$ the decompositions (4.6) and (4.7) are found asymptotically. For $\varepsilon \rightarrow 0$ they approximate $L$ and $U$ up to $O(\varepsilon)$. Therefore, for $\pi / 4<\alpha<\pi$, the ILU-decomposition $L U$ is an accurate approximation to $L_{h, \varepsilon}$ for small $\varepsilon$. Hence ILU is a good smoother (only) in these cases.

To explain the small smoothing factor for the ILLU relaxation we consider (2.5) -(2.6) and we introduce the molecules

$$
\begin{array}{ll}
L^{*} & =[0, \\
D^{*} & =[c(s-c), \\
U^{*} & =[-s c, \\
& 2-2 c s, \\
c & c(s-c)]
\end{array},
$$

We compute $\overline{\mathrm{D}}^{\star}$ from $\overline{\mathrm{D}}^{*} *\left(\overline{\mathrm{D}}^{\star}-\mathrm{D}^{\star}\right)+\mathrm{L}^{*} * \mathrm{U}^{*}=0$ and obtain

$$
\bar{D}^{\star}=\left[c(s-c),(c-s)^{2}+c^{2}, c(s-c)\right]
$$

This $\overline{\mathrm{D}}^{*}$ corresponds to a tridiagonal matrix and has a bounded inverse for all $\alpha$. Therefore, it is also a solution of

$$
\overline{\mathrm{D}}^{\star}=\mathrm{D}^{\star}-\underline{\operatorname{tridiag}}\left(\mathrm{L}^{*} *\left(\overline{\mathrm{D}}^{\star}\right)^{-1} * \mathrm{U}^{*}\right),
$$

and we find that this ILU-decomposition is exact for $\varepsilon=0$ :

$$
\widetilde{\mathrm{L}}_{\mathrm{h}, 0}^{*}=\left(\mathrm{L}^{*}+\bar{D}^{*}\right)\left(\overline{\mathrm{D}}^{*}\right)^{-1}\left(\overline{\mathrm{D}}^{*}+\mathrm{U}^{*}\right)=\mathrm{L}^{*}+\mathrm{D}^{*}+\mathrm{U}^{*}=\mathrm{L}_{\mathrm{h}, 0}^{*}
$$

For small $\varepsilon$ the ILLU-decomposition algorithm generates this decomposition asymptotically (away from the boundary). This explains why ILLU is an excellent smoother for $\operatorname{small} \varepsilon$ and all $\alpha$.

## 5. THE CONVECTION DIFFUSION EQUATION

The direct application of the standard FEM to equation (1.3) yields inadequate discretizations for small $\varepsilon / h[3,13,18]$. The same is true for central differences. Therefore, either direction-dependent (upwind-) differences are used or an artificial diffusion is introduced. For the solution of the discrete systems the MG-method can
be applied. However, due to the special character of the equations, typical difficulties may arise. These have been studied for upwind differences in $[5,12,16]$ and for artificial diffusion in [4,5,22].

In this section we make some remarks on the application of artificial diffusion. In section 6 we consider a MG-variant consistent with the Streamline-Upwind FE$\operatorname{method}[7,14]$.

Molecules for the discretization of (1.3) are given by

$$
\begin{equation*}
L_{\gamma, h}^{*}=\gamma\left(A_{11}^{*}+A_{22}^{*}\right)+\frac{h c}{6}\left(A_{1}^{*}+p A_{3}^{*}\right)+\frac{h s}{6}\left(A_{2}^{*}-p A_{3}^{*}\right) \tag{5.1}
\end{equation*}
$$

For finite elements $p=0$, for central differences $p=1 ; \gamma=\gamma(h)=\varepsilon+\beta h$ is the diffusion coefficient, $\beta$ or $\beta(h)$ is the coefficient of artificial diffusion.

The symbol of $L_{\gamma, h}$ is given by

$$
\begin{equation*}
\hat{\mathrm{L}}_{\gamma, \mathrm{h}}(\phi, \theta)=4 \gamma\left[\sin ^{2}(\phi / 2)+\sin ^{2}(\theta / 2)\right]+\operatorname{ihT}(\phi, \theta), \tag{5.2}
\end{equation*}
$$

with

$$
\begin{align*}
T(\phi, \theta)= & c \sin (\phi / 2)[2 \cos (\phi / 2)+(1-p) \cos (\theta-\phi / 2)]  \tag{5.3}\\
& +s \sin (\theta / 2)[2 \cos (\theta / 2)+(1-p) \cos (\phi-\theta / 2)]
\end{align*}
$$

For the continuous operator (1.3) we have

$$
\hat{\mathrm{L}}_{\varepsilon}(\phi, \theta)=\varepsilon\left(\phi^{2}+\theta^{2}\right)+\operatorname{ih}(c \phi+s \theta)
$$

Hence, for (1.3) with $\varepsilon=0$, unstable modes $u_{\phi, \theta}$ exist for ( $\phi, \theta$ ) with $c \phi+s \theta=0$. I.e. the reduced continuous operator has one set of unstable modes. (In the solution these components are determined by the inflow boundary data.) For (5.2) with $\gamma=0$ we find two branches of unstable modes. A branch of spurious unstable modes is found in the high frequency domain (figure 5.1). This implies that relaxation methods of the form (2.4) do not damp these high frequency components.

Fig. 5.1

From (5.2) it follows that the discretization (5.1) is stable if $\gamma \geq \mathrm{Ch}>0$
(cf. [22]). For such stable discretizations the existence of a relaxation method which damps the high frequencies in the error is guaranteed (cf. [6]). It is of practical
importance to find relaxations that work efficiently. To compare the effect of some relaxations, in table 5.1 we give smoothing factors for zebra, ILU and ILLU relaxation, when applied to (5.1) with $p=0 ; \gamma(h)=\varepsilon+\beta h ; \varepsilon=0 ; \beta=0.5$, 1 .

|  | zebra |  | ILU |  | ILLU |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\alpha$ | $\beta=0.5$ | $\beta=1.0$ | $\beta=0.5$ | $\beta=1.0$ | $\beta=0.5$ | $\beta=1.0$ |
| $0^{\circ}$ | 0.711 | 0.280 | 0.0777 | 0.0937 | 0.0221 | 0.0257 |
| $30^{\circ}$ | 0.584 | 0.245 | 0.0148 | 0.0837 | 0.0021 | 0.0366 |

| $90^{\circ}$ | 0.252 | 0.250 | 0.195 | 0.127 | 0.1063 | 0.0746 |
| $120^{\circ}$ | 0.290 | 0.260 | 0.237 | 0.139 | 0.0674 | 0.0607 |
| $150^{\circ}$ | 0.573 | 0.263 | 0.160 | 0.123 | 0.0324 | 0.0364 |

Table 5.1 Smoothing rates for FE discretization of (1.3) with $\varepsilon=0$ and with artificial diffusion $\gamma=\beta$.

In the MGM not only the smoothing should efficiently damp the high frequencies in the error, but also the CGC should work properly to reduce the low frequencies. For equation (1.3) this CGC needs special attention. From section 3 we know that application of (2.2) to $L_{\gamma(h), h}$, with $P_{h H}$ and $\bar{R}_{H h}$ given by (3.3), yields on a coarser level

$$
\bar{R}_{2 h, h}{ }^{L}(h), h^{P} h, 2 h=L_{\gamma(h), 2 h},
$$

i.e. the FE discrete operator on the grid 2 h with diffusion coefficient $\gamma(\mathrm{h})$. This means that the Galerkin approximation gives an amount of diffusion on the coarse grids that is equal to the amount used at the finer grids. When repeatedly applied, this produces a FE discretization with negligible artificial diffusion on the coarsest grids. Hence, the coarser grid operators become unstable, and diverging corrections will appear in the CGCs.

To avoid the unstable Galerkin approximations, we can discretize the problem on each grid - with meshsize $H$ - with a corresponding artificial diffusion $\gamma(H)$. This is studied in [22], where suggestions are given for the choice of $\gamma(h)$ on the different levels. However, the lack of consistency between the diffusion terms in the discrete operators affects the convergence rate of the CGC. By the same argument as used in [5, p40], it is found that the reduction of some low-frequency components is only by a factor $(\gamma(H)-\gamma(h)) / \gamma(H)$ when in a CGC the operators $L_{\gamma(h), h}$ and $L_{\gamma(H), H}$ are used.

## 6. A STREAMLINE-UPWIND RESTRICTION FOR THE CONVECTION DIFFUSION EQUATION

In this section we introduce a new, asymmetric restriction. This restriction is
applied in combination with the Streamline-Upwind Petrov-Galerkin (SU-PG) FE method of discretization $[7,14]$ and, in fact, it is the discrete analogue of the asymmetric weight-function in that method. With this $\bar{R}_{H h}$ in (2.2) we obtain Galerkin coarse grid operators that are again of the Streamline-Upwind type. Other asymmetric restrictions have been studied for finite difference methods in $[1,12,16]$. These restrictions satisfy $\bar{R}_{\mathrm{Hh}}=\mathrm{P}_{\mathrm{hH}}^{\mathrm{T}}$ where the interpolation $\mathrm{P}_{\mathrm{hH}}$ is deduced from the difference equation (matrix-weighted interpolation). The comparison of the different asymmetric methods might be the subject of future study. Here, with the new restriction, we remain consistent with the Petrov-Galerkin approach [7,14]: the prolongation is kept unchanged and only the restriction is adapted to the differential equation.

The SU-PG method is a FE method for the solution of (1.1) with trialfunctions $S^{h}=\operatorname{span}\left\{\phi_{j}^{h}\right\}$ and testfunctions $V^{h}=\operatorname{span}\left\{\phi_{j}^{h}+k \bar{b} \nabla \phi_{j}^{h}\right\}$. The functions $\phi_{j}^{h}$ are standard FE basis-functions. We apply the method with piecewise linear $\phi_{j}^{h}$ on the triangularization $T^{h} ; k=k(h, \varepsilon)$ is a scalar parameter. It can be shown [11] that a good choice of $k(h, \varepsilon)$ should satisfy

$$
k(h)=O(h) \text { if } \varepsilon / h \leq C, k(h)=O\left(h^{2} / \varepsilon\right) \text { if } \varepsilon / h \geq C
$$

For (1.3) we obtain the discrete equations

$$
\begin{equation*}
\sum_{j} \mathrm{~B}\left(\phi_{i}, \phi_{j}\right) \mathrm{u}_{j}^{\mathrm{h}}=\ell\left(\phi_{i}\right) \tag{6.1}
\end{equation*}
$$

where

$$
\begin{align*}
& B\left(\phi_{i}, \phi_{j}\right)=\sum_{e} \int \nabla \phi_{i}\left(\varepsilon I+k \bar{b}^{-T} \bar{b}\right) \nabla \phi_{j}+\phi_{i} \bar{b} \nabla \phi_{j} d \Omega_{e}  \tag{6.2}\\
& l\left(\phi_{i}\right)=\sum_{e} \int_{i}\left(\phi_{i}+k \bar{b} \nabla \phi_{i}\right) f d \Omega_{e} . \tag{6.3}
\end{align*}
$$

The differences with standard FEM are:

1) an anisotropic (streamline directed) artificial diffusion appears:

$$
\begin{equation*}
\overline{\bar{\gamma}}(h)=\varepsilon I+k(h) \bar{b}^{T} \bar{b} ; \tag{6.4}
\end{equation*}
$$

2) the functions in the space $Y$ are weighted by an asymmetric (upwind weighted) weight function.
The weighting of the space $Y$ defines an asymmetric restriction $\bar{R}_{h}$ and for a piecewise polynomial approximation of functions in $Y$, restriction molecules can be derived. For instance, if $Y$ is approximated by piecewise linear functions on $T_{h}$, this restriction molecule reads

$$
\begin{equation*}
\bar{R}_{h}^{*}=\frac{h^{2}}{6}\left\{\frac{1}{2} A_{0}^{*}+k b_{1} A_{1}^{*}+k b_{2} A_{2}^{*}\right\} \tag{6.5}
\end{equation*}
$$

This asymmetric molecule suggests an asymmetric restriction $\overline{\mathrm{R}}_{\mathrm{Hh}}$ with a molecule

$$
\begin{equation*}
\overline{\mathrm{R}}_{\mathrm{Hh}}^{\star}=\mathrm{P}_{\mathrm{hH}}^{*}+\mu_{1}\left(\mathrm{~A}_{1}^{*}+\mathrm{pA}_{3}^{*}\right)+\mu_{2}\left(\mathrm{~A}_{2}^{*}-\mathrm{pA}_{3}^{*}\right) \tag{6.6}
\end{equation*}
$$

(e.g. $p=0$ or $p=1$ ). The difference molecule corresponding with the discrete operator (6.2) reads

$$
\begin{equation*}
h_{L}^{2} L_{h}^{*}=\gamma_{11} A_{11}^{*}+\gamma_{12} A_{12}^{*}+\gamma_{22} A_{22}^{*}+\frac{h b_{1}}{6} A_{1}^{*}+\frac{h b_{2}}{6} A_{2}^{*} . \tag{6.7}
\end{equation*}
$$

When (6.6), (6.7) and (3.3) are used for the construction of a Galerkin approximation (2.2) we find the molecule

$$
\begin{align*}
(2 \mathrm{~h})^{2} \overline{\mathrm{R}}_{\mathrm{Hh}}^{*} * \mathrm{~L}_{\mathrm{h}}^{*} * \mathrm{P}_{\mathrm{hH}}^{*} & =\left(\gamma_{11}-\frac{3 \mathrm{~h} \mu_{1} \mathrm{~b}_{1}}{2}\right) A_{11}^{*}+\left(\gamma_{12}-\frac{3 \mathrm{~h}}{2} \frac{{ }_{1} \mathrm{~b}_{2}+\mu_{2}{ }_{1}}{2}\right) A_{12}^{*}+  \tag{6.8}\\
& +\left(\gamma_{22}-\frac{3 \mathrm{~h}}{2} \mu_{2} \mathrm{~b}_{2}\right) \mathrm{A}_{22}^{*}+\frac{\mathrm{h}}{3}\left(\mathrm{~b}_{1} A_{1}^{*}+\mathrm{b}_{2} \mathrm{~A}_{2}^{*}\right)+\mathrm{r}(\overrightarrow{\mathrm{~b}}, \mathrm{p}) A_{3}^{*} .
\end{align*}
$$

This is a discretization on the mesh $H=2 h$ of the same form as (6.7) except for the remainder term $r(\vec{b}, p) A_{3}^{*}$. We see that (6.8) has the additional amount of artificial diffusion

$$
\gamma(2 h)-\gamma(h)=-\frac{3 h}{2}\left(\left(_{b_{2}}^{b_{2}}\right)\left(\mu_{1}, \mu_{2}\right) .\right.
$$

This is accounted for by the $h$-dependence of the parameter $k$. For (6.7) and (6.8) to be consistent with (6.4) the following relation is to be satisfied

$$
[k(2 h)-k(h)] \bar{b}^{T} \bar{b}=\frac{-3 h}{2}\left(b_{b_{2}}^{b_{1}}\right)\left(\mu_{1}, \mu_{2}\right) .
$$

Introducing the notation $\mu_{j}=-\frac{2}{3} \mu(h) b_{j}, j=1,2$, this relation reads

$$
\begin{equation*}
k(2 h)-k(h)=h \mu(h) . \tag{6.9}
\end{equation*}
$$

Thus, our restriction (6.6) is upwind weighted and equation (6.9) shows how the parameters $\mu_{k}$ in the asymmetric restriction are related to the choice of the artificial streamline-diffusion parameter $k(h)$.

With this asymmetric $\bar{R}_{H h}$ we expect the MGM to improve for the SU-PG discretization of (1.3) because (i) the CGCs use streamline-upwind Galerkin approximations as coarse grid operators and (ii) by the asymmetric restriction downstream residuals have less upstream influence.

An experiment was made to see the effects. The problem (1.3) was solved for $\varepsilon=10^{-3}$, on the unit square, using a MGM cycle with ( $p, q, s$ ) $=(1,0,2)$ and with 5 levels of discretization ( $h=1 / 32$ on the finest mesh; $k(h)=2 h / 3$ ). Both the solution and the initial error were smooth. To see the effect of the new CGC a relaxation was used (zebra) with little capacity to reduce the low frequency error in the direction $\alpha=0^{\circ}$ or $180^{\circ}$. Another experiment was made with the ILLU-relaxation (table 6.1).

Table 6.1 Residual convergence factors

$$
\sqrt[3]{\left\|f_{h}-L_{h} u_{h}^{(2)}\right\|_{2} /\left\|f_{h}-L_{h} u_{h}^{(5)}\right\|_{2}} .
$$

Table 6.1 shows that the Galerkin approximation (2.2) with the symmetric $\bar{R}_{\mathrm{Hh}}$, eq. (3.3), may diverge indeed. When the asymmetric $\overline{\mathrm{R}}_{\mathrm{Hh}}$, eq. (6.6), is used, little difference is seen between the CGCs with discretizations (2.2) or (6.2), as was expected from (6.8). In the case of zebra-relaxation the use of the asymmetric restriction has a positive effect. (Similar results were obtained for problems with boundary layers.) If we use the more powerful ILLU-relaxation, we see that the new CGC becomes of little importance. It even has an adverse effect. Now Galerkin approximation with the symmetric $\overline{\mathrm{R}}_{\mathrm{Hh}}$ shows the best convergence rate. (This effect may disappear if more levels of discretization are used, cf. [22].) Apparently the ILLUrelaxation reduces the total error very efficiently. It also takes care of the low frequency components that are produced by the less stable (and more accurate) CGC obtained by the symmetric Galerkin approximation. This effect is seen for all flow directions $\alpha$.
