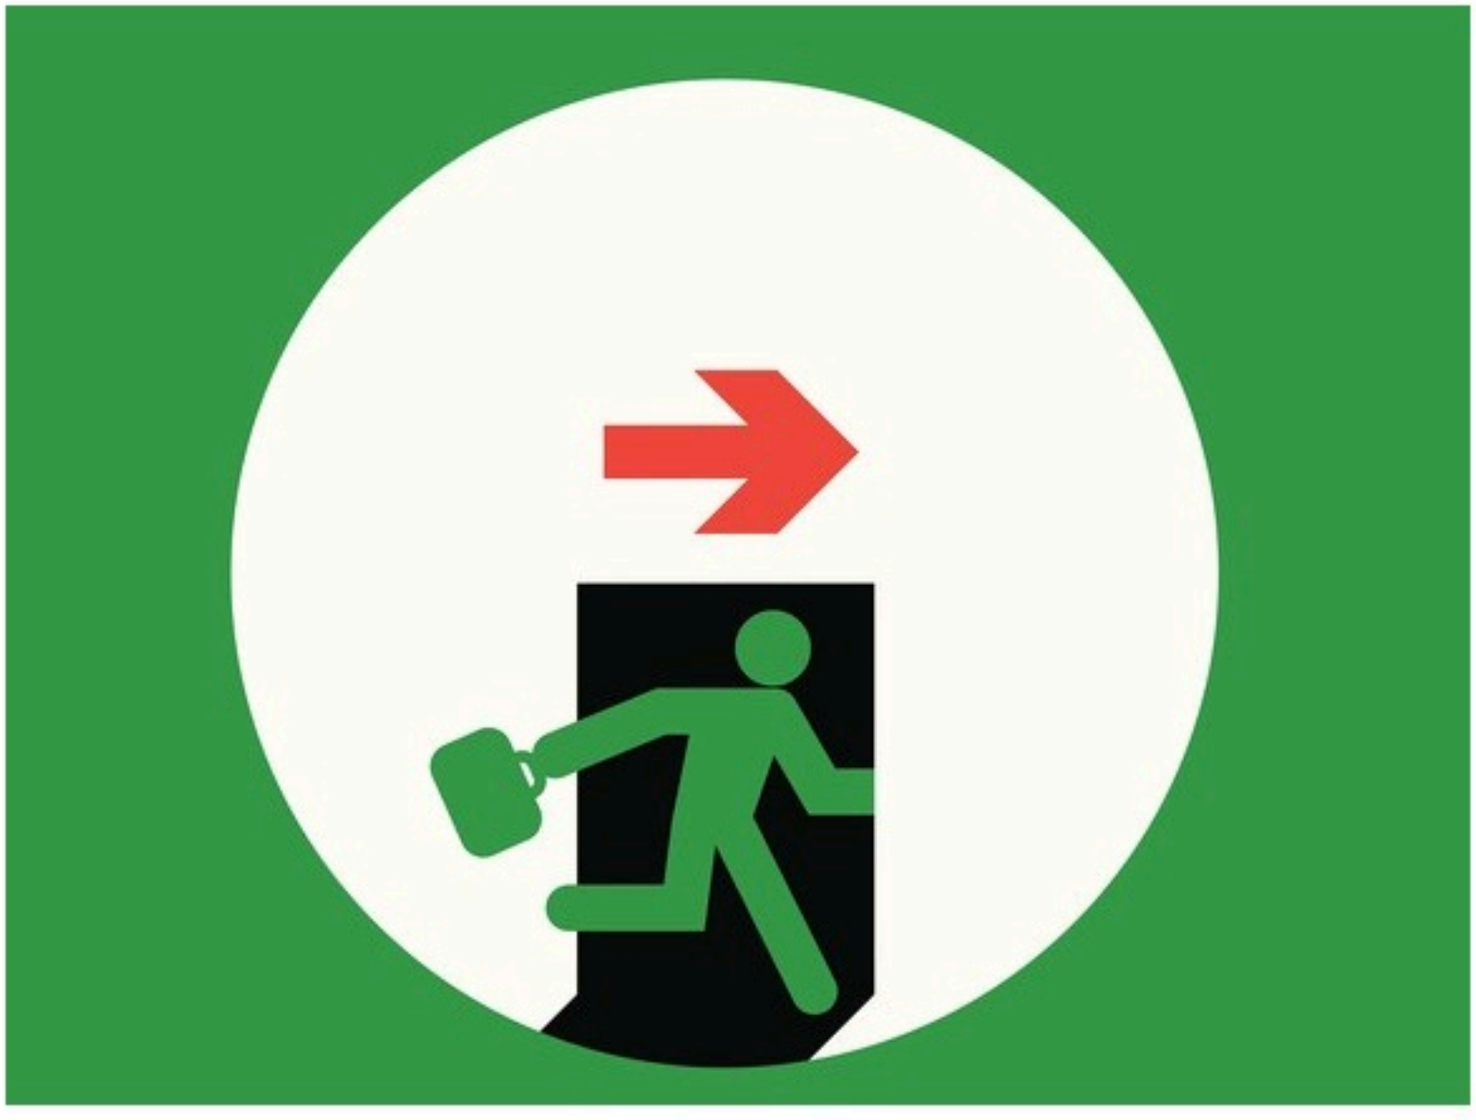
A $50 MILLION HACK JUST SHOWED THAT THE DAO WAS ALL TOO HUMAN



Thoughts on The DAO Hack

Emin Gün Sirer

dao ethereum

June 17, 2016 at 09:45 AM

← Older

Newer →

We just lived through the nightmare scenario we were worried about as we called for a moratorium on The DAO: someone exploited a weakness in the code of The DAO to empty out more than 2M ($40M USD) ether.

The exploit seems to have targeted the *reentrancy problem* in the 'splitDAO' function. The reentrancy problem is related to but distinct from the unchecked-send problem that was discussed on this blog yesterday. Both problems are well-known, identified by Least Authority's audit of the Ethereum virtual machine as problems that can affect applications, as well as Peter Vessenes's recent blog post. In essence, a call that looks like a regular call can easily be turned into a recursive call, and unless the application is coded very carefully, it can be used to make multiple withdrawals when only one should be allowed. It looks like the attacker took advantage of it to withdraw substantial sums.

2. Parity Wallet Breach

Issues began in July when the U.K.-based startup discovered a vulnerability in version 1.5 of its wallet software, resulting in at least 150,000 ethers being stolen from user accounts.

4. Parity Wallet Freeze

Occurring suddenly this November, a Parity user accidentally found a bug in the software code, freezing more than $275 million in ether in the wallet's second major incident of 2017.

BUG

```
/* Allow another contract to spend some tokens in your behalf */
function approve(address _spender, uint256 _value)
    returns (bool success) {
    allowance[msg.sender][_spender] = _value;
    return true;
}

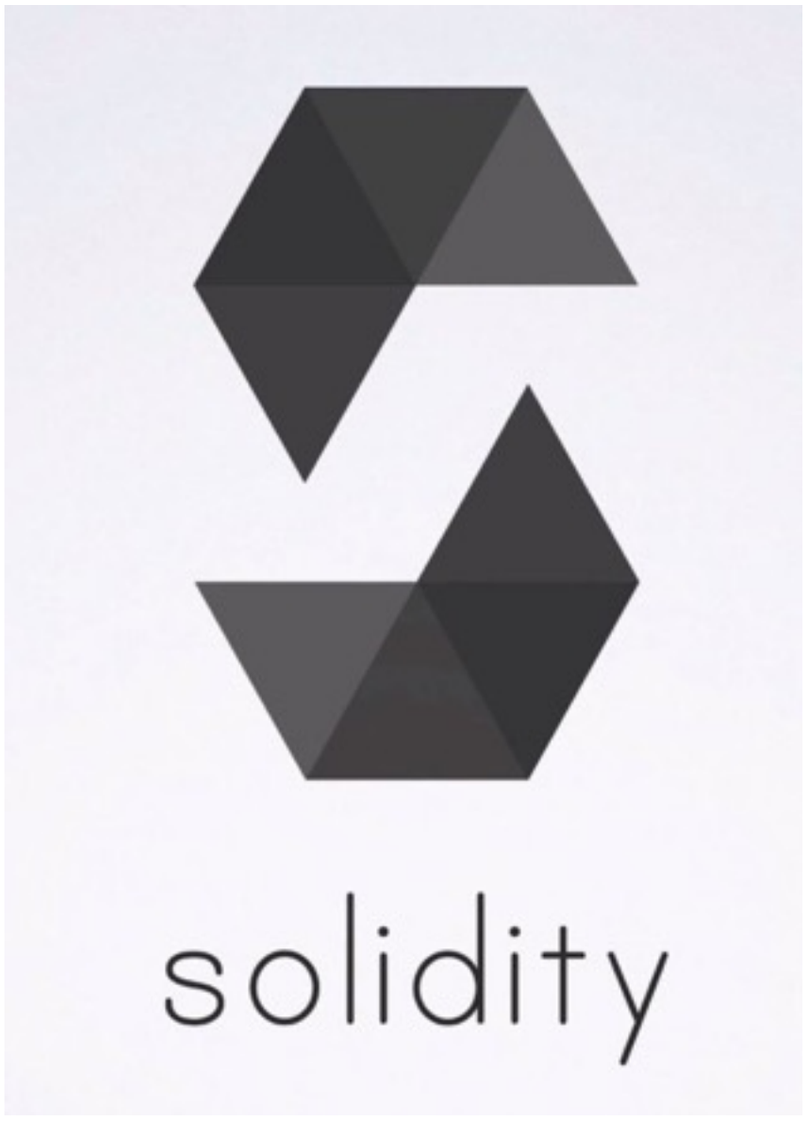
/* Approve and then comunicate the approved contract in a single tx */
function approveAndCall(address _spender, uint256 _value, bytes _extraData)
    returns (bool success) {
    tokenRecipient spender = tokenRecipient(_spender);
    if (approve(_spender, _value)) {
        spender.receiveApproval(msg.sender, _value, this, _extraData);
        return true;
    }
}
```

```
/* A contract attempts to get the coins */
function transferFrom(address _from, address _to, uint256 _value) returns (bool success) {
    if (balanceOf[_from] < _value) throw;                 // Check if the sender has enough
    if (balanceOf[_to] + _value < balanceOf[_to]) throw;  // Check for overflows
    if (_value > allowance[_from][msg.sender]) throw;   // Check allowance
    balanceOf[_from] -= _value;                           // Subtract from the sender
    balanceOf[_to] += _value;                             // Add the same to the recipient
    allowance[_from][msg.sender] -= _value;
    Transfer(_from, _to, _value);
    return true;
}

/* This unnamed function is called whenever someone tries to send ether to it */
function () {
    throw;     // Prevents accidental sending of ether
}
```

Features of Solidity

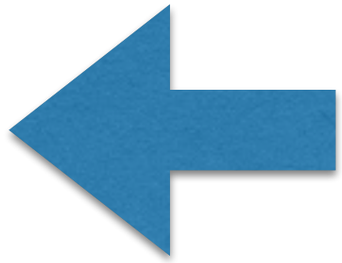
- Javascript - objects + “stuff”
  - functional abstraction
  - conditionals
  - recursion
  - loops
  - execution handling
  - side-effects



☆ MadMax: Surviving Out-of-Gas Conditions in Ethereum Smart Contracts

OOPSLA

Session: Security Chair(s): Tobias Wrigstad



!!!!

Ethereum is a distributed blockchain platform, serving as an ecosystem for smart contracts: full-fledged inter-communicating programs that capture the transaction logic of an account. Unlike programs in mainstream languages, the execution of an Ethereum smart contract is restricted by a gas limit: execution proceeds as long as gas is available. Thus, gas is a valuable resource that can be manipulated by an attacker to provoke unwanted behavior in a victim's smart contract (e.g., wasting or blocking funds of said victim). Gas-focused vulnerabilities exploit undesired behavior when a contract (directly or through other interacting contracts) runs out of gas. Such vulnerabilities are among the hardest for programmers to protect against, as out-of-gas behavior may be uncommon in non-attack scenarios and reasoning about it is far from trivial. In this paper, we classify and identify gas-focused vulnerabilities, and present MadMax: a static program analysis technique to automatically detect gas-focused vulnerabilities with very high confidence. Our approach combines a control-flow-analysis-based decompiler and declarative program-structure queries. The combined analysis captures high-level domain-specific concepts (such as "dynamic data structure storage" and "safely resumable loops") and achieves high precision and scalability. MadMax analyzes the entirety of smart contracts in the current Ethereum blockchain in just 10 hours (with decompilation timeouts in 8% of the cases) and flags contracts with a current (though highly volatile) monetary value of over $5B as vulnerable. Manual inspection of a sample of flagged contracts shows that 81% of the sampled warnings do indeed lead to vulnerabilities, which we report on in our experiment.

SMART CONTRACTS ARE NEITHER SMART NOR CONTRACTS

FRITZ HENGLEIN
UNIVERSITY OF COPENHAGEN

http://hjemmesider.diku.dk/~henglein/smart-contracts-are-neither.pdf

- Smart contracts = self-executing contracts (programs) in complex Turing-complete programming language

- Rules and actions intermixed:
  Not contracts

- Hard to analyze, low-level programs:
  Not smart

Programming

A Formal Language for Analyzing Contracts

```
future(rightA="1 round lot pork bellies",
       rightB="$1,500.00",
       p = "for delivery in July 2002") =

    when withinPeriod(p)
        to Holder rightA   with   to Counterparty rightB
    then terminate
```

```
callOptionAmerican (rightA="1 round lot XYZ Corp.",
                    rightB="$2,000/lot",
                    time="end of trading on last trading day of August") =
    when beforeTime(time)
        when choiceOf(Holder)
            to Holder rightA with to Counterparty rightB
    when afterTime(time)
        terminate
```

```
loanPayments(payment, schedule) =
    for schedule
        when withinPeriod(schedule.next)
            payment
carPurchase(car, downPayment, monthlyPayment, schedule)  =
    to Counterparty getTitle(car)   with   to Holder downPayment
    then to Holder loanPayment(monthlyPayment, schedule)
```

Domain-specific smart contract languages

```
/* Allow another contract to spend some tokens in your behalf */
function approve(address _spender, uint256 _value)
    returns (bool success) {
    allowance[msg.sender][_spender] = _value;
    return true;
}

/* Approve and then comunicate the approved contract in a single tx */
function approveAndCall(address _spender, uint256 _value, bytes _extraData)
    returns (bool success) {
    tokenRecipient spender = tokenRecipient(_spender);
    if (approve(_spender, _value)) {
        spender.receiveApproval(msg.sender, _value, this, _extraData);
        return true;
    }
}

/* A contract attempts to get the coins */
function transferFrom(address _from, address _to, uint256 _value) returns (bool success) {
    if (balanceOf[_from] < _value) throw;                 // Check if the sender has enough
    if (balanceOf[_to] + _value < balanceOf[_to]) throw;  // Check for overflows
    if (_value > allowance[_from][msg.sender]) throw;   // Check allowance
    balanceOf[_from] -= _value;                           // Subtract from the sender
    balanceOf[_to] += _value;                             // Add the same to the recipient
    allowance[_from][msg.sender] -= _value;
    Transfer(_from, _to, _value);
    return true;
}

/* This unnamed function is called whenever someone tries to send ether to it */
function () {
    throw;     // Prevents accidental sending of ether
`
```
