PSIDE Users' Guide

W.M. Lioen, J.J.B de Swart, W.A. van der Veen

Modelling, Analysis and Simulation (MAS)

MAS-R9834 December 1998
ABSTRACT
PSIDE – Parallel Software for Implicit Differential Equations – is a code for solving implicit differential equations on shared memory parallel computers. In this paper we describe the user interface.

Keywords and Phrases: numerical software, parallel computers, IVP, IDE, ODE, DAE.
Note: The maintenance of PSIDE belongs to the project MAS2.2: ‘Parallel Software for Implicit Differential Equations’.
Acknowledgements: This work is supported financially by the ‘Technologiestichting STW’ (Dutch Foundation for Technical Sciences), grants no. CWI.2703, CWI.4533. The use of supercomputer facilities was made possible by the ‘Stichting Nationale Computerfaciliteiten’ (National Computing Facilities Foundation, NCF), with financial support from the ‘Nederlandse Organisatie voor Wetenschappelijk Onderzoek’ (Netherlands Organization for Scientific Research, NWO).
Note: The latest version of PSIDE and this document can always be found at [SL V98a].

1. Introduction
PSIDE solves Implicit Differential Equations (IDEs) of the form

\[ g(t, y, y') = 0, \quad g, y \in \mathbb{R}^d, \]
\[ t_0 \leq t \leq t_{\text{end}}, \quad y(t_0) = y_0, \quad y'(t_0) = y_0', \]

(1.1)

were \( y_0 \) and \( y_0' \) are such that \( g(t_0, y_0, y_0') = 0 \) (for higher-index problems the initial values have to satisfy more conditions; see §4). It uses the four-stage Radau IIA method. The nonlinear systems are solved by a modified Newton process, in which every Newton iterate itself is computed by means of the Parallel Iterative Linear system Solver for Runge–Kutta (PILSRK) proposed in [HS97]. This process is constructed such that the four stage values can be computed simultaneously, thereby making PSIDE suitable for execution on four processors; see §7 for installation instructions. Full details about the algorithmic choices and the implementation of PSIDE can be found in [SLV98b].
2. Subroutine heading of PSIDE

PSIDE is a Fortran 77 routine, whose heading reads

```fortran
SUBROUTINE PSIDE(NEQN,Y,DY,GEVAL,
+ JNUM,NLJ,NUJ,JEVAL,
+ MNUM,NLM,NUM,MEVAL,
+ T,TEND,RTOL,ATOL,IND,
+ LRWORK,RWORK,LIWORK,IWORK,
+ RPAR,IPAR,IDID)

INTEGER NEQN,NLJ,NUJ,NLM,NUM,IND(*),LRWORK,LIWORK,
+ IWORK(LIWORK),IPAR(*),IDID
DOUBLE PRECISION Y(NEQN),DY(NEQN),T,TEND,RTOL(*),ATOL(*),
+ RWORK(LRWORK),RPAR(*)
LOGICAL JNUM,MNUM
EXTERNAL GEVAL,JEVAL,MEVAL
```

The variables listed under `INTENT(IN)`, `INTENT(INOUT)`, and `INTENT(OUT)` are input, update and output variables, respectively.

3. Arguments

**NEQN**

On entry, this is the dimension $d$ of the IDE (1.1), the number of equations to be solved.

**Y(NEQN)**

On entry, this array contains the initial value $y_0$.

On exit, $Y$ contains $y(T)$, the computed solution approximation at $T$.

(After successful return, $T = TEND$.)

**DY(NEQN)**

On entry, this array contains the initial value $y'_0$.

On exit, $DY$ contains $y'(T)$, the computed derivative approximation at $T$.

(After successful return, $T = TEND$.)

**GEVAL**

This is the subroutine which you provide to define the IDE

```fortran
SUBROUTINE GEVAL(NEQN,T,Y,DY,G,IERR,RPAR,IPAR)

INTEGER NEQN,IERR,IPAR(*)
DOUBLE PRECISION T,Y(NEQN),DY(NEQN),G(NEQN),RPAR(*)

C INTENT(IN) NEQN,T,Y,DY
C INTENT(INOUT) IERR,RPAR,IPAR
C INTENT(OUT) G
```

For the given values of $T$, $Y$, and $DY$ the subroutine should return the residual of the IDE

$$G = g(T,Y,DY).$$
3. Arguments

You must declare the name GEVAL in an external statement in your program that calls PSIDE. IERR is an integer flag which is always equal to zero on input. Subroutine GEVAL should set IERR = -1 if GEVAL can not be evaluated for the current values of Y and DY. PSIDE will then try to prevent IERR = -1 by using a smaller stepsize.

All other parameters have the same meaning as within subroutine PSIDE.

JNUM

To solve the IDE it is necessary to use the partial derivatives \( J = \partial g/\partial y \). The solution will be more reliable if you provide \( J \) via the subroutine JEVAL, in this case set JNUM = .FALSE.. If you do not provide a subroutine to evaluate \( J \), provide a dummy JEVAL, set JNUM = .TRUE. and PSIDE will approximate \( J \) by numerical differencing.

NLJ and NUJ

If \( J \) is a full matrix, set NLJ = NEQN, otherwise set NLJ and NUJ equal to the lower bandwidth and upper bandwidth of \( J \), respectively.

JEVAL

This is the subroutine which you provide to define \( J \) (if JNUM .EQ. .FALSE.)

SUBROUTINE JEVAL(LDJ,NEQN,NLJ,NUJ,T,Y,DY,DGDY,RPAR,IPAR)
INTEGER LDJ,NEQN,NLJ,NUJ,IPAR(*)
DOUBLE PRECISION T,Y(NEQN),DY(NEQN),DGDY(LDJ,NEQN),RPAR(*)
C INTENT(IN) LDJ,NEQN,NLJ,NUJ,T,Y,DY
C INTENT(INOUT) RPAR,IPAR
C INTENT(OUT) DGDY

For the given values of \( T \), \( Y \), and \( DY \) the subroutine should return the partial derivatives, such that

- \( DGDY(I,J) \) contains \( \partial g(I,T,Y,DY)/\partial y_J \) if \( J \) is a full matrix (NLJ = NEQN);
- \( DGDY(I-J+NUJ+1,J) \) contains \( \partial g(I,T,Y,DY)/\partial y_J \) if \( J \) is a band matrix (0 \( \leq \) NLJ < NEQN) (LAPACK / LINPACK / BLAS storage).

You must declare the name JEVAL in an external statement in your program that calls PSIDE. LDJ denotes the leading dimension of \( J \).

All other parameters have the same meaning as within subroutine PSIDE.

MNUM

To solve the IDE it is necessary to use the partial derivatives \( M = \partial g/\partial y' \). The solution will be more reliable if you provide \( M \) via MEVAL, in this case set MNUM = .FALSE.. If you do not provide a subroutine to evaluate \( M \), provide a dummy MEVAL, set MNUM = .TRUE. and PSIDE will approximate \( M \) by numerical differencing.

NLM and NUM

If \( M \) is a full matrix, set NLM = NEQN, otherwise set NLM and NUM equal to the lower bandwidth and upper bandwidth of \( M \), respectively. It is supposed that NLM .LE. NLJ and NUM .LE. NUJ.

MEVAL

This is the subroutine which you provide to define \( M \) (if MNUM .EQ. .FALSE.)
For the given values of $T$, $Y$, and $DY$ the subroutine should return the partial derivatives, such that

- $DGDDY(I,J)$ contains $\frac{\partial g_I(T,Y,DY)}{\partial y'_J}$ if $M$ is a full matrix ($NLM = NEQN$);
- $DGDDY(I-J+NUM+1,J)$ contains $\frac{\partial g_I(T,Y,DY)}{\partial y'_J}$ if $M$ is a band matrix ($0 \leq NLM < NEQN$) (LAPACK / LINPACK / BLAS storage).

You must declare the name `MEVAL` in an external statement in your program that calls `PSIDE`.

$LDM$ denotes the leading dimension of $M$.

All other parameters have the same meaning as within subroutine `PSIDE`.

$T$

On entry, $T$ must specify $t_0$, the initial value of the independent variable.  
On successful exit ($IDID .EQ. 1$), $T$ contains $TEND$.  
On an error return, $T$ is the point reached.

$TEND$

On entry, $TEND$ must specify the value of the independent variable at which the solution is desired.

$RTOL$ and $ATOL$

You must assign relative $RTOL$ and absolute $ATOL$ error tolerances to tell the code how small you want the local errors to be.  You have two choices

- both $RTOL$ and $ATOL$ are scalars (set $IWORK(1) = 0$): the code keeps, roughly, the local error of $Y(I)$ below $RTOL*ABS(Y(I))+ATOL$;
- both $RTOL$ and $ATOL$ are vectors (set $IWORK(1) = 1$): the code keeps the local error of $Y(I)$ below $RTOL(I)*ABS(Y(I))+ATOL(I)$.

In either case all components must be non-negative.

$IND$

If $IWORK(2) .EQ. 1$, then $IND$ should be declared of length $NEQN$ and $IND(I)$ must specify the index of variable $I$. If $IWORK(2) .EQ. 0$, then $IND$ is not referenced and the problem is assumed to be of index 1.  
See §4 for information how to determine the index of variables of certain problem classes.

$LRWORK$

On entry $LRWORK$ must specify the length of the $RWORK$ array.  You must have for the full partial derivatives case (when $NLJ = NEQN$)

$$LRWORK \geq 20 + 27*NEQN + 6*NEQN^2$$,

for the case where $M$ is banded and $J$ is full (when $NLJ = NEQN$ and $NLM < NEQN$)

$$LRWORK \geq 20 + (27 + NLM*NUM+1 + 5*NEQN)*NEQN$$,
and for the case where both partial derivatives are banded (when NLJ < NEQN)

\[ \text{LRWORK} \geq 20 + (27 + NLJ+NUJ+NLM+NUM+2 + 4*(2*NLJ+NUJ+1))*NEQN. \]

**RWORK**

Real work array of length LRWORK. RWORK(1),...,RWORK(20) serve as parameters for the code. For standard use, set RWORK(1),...,RWORK(20) to zero before calling.

On entry:
- if RWORK(1) .GT. 0D0 then PSIDE will use RWORK(1) as initial stepsize instead of determining it internally.

On exit:
- RWORK(1) contains the stepsize used on the last successful step.

**LIWORK**

On entry LIWORK must specify the length of the IWORK array. You must have

\[ \text{LIWORK} \geq 20 + 4*NEQN. \]

**IWORK**

Integer work array of length LIWORK. IWORK(1),...,IWORK(20) serve as parameters for the code. For standard use, set IWORK(1),...,IWORK(20) to zero before calling.

On entry:
- if IWORK(1) .EQ. 1 then RTOL and ATOL are vectors instead of scalars,
- if IWORK(2) .EQ. 1 then IND is a vector,
- set IWORK(10) = 0 if PSIDE is called for the first time; for subsequent calls of PSIDE do not reinitialize the parameters IWORK(10),...,IWORK(19) to zero.

On exit:
- IWORK(10) contains the number of successive PSIDE calls,
- IWORK(11) contains the number of g evaluations,
- IWORK(12) contains the number of J and M evaluations (J and M are computed in tandem and count as 1),
- IWORK(13) contains the number of LU-decompositions,
- IWORK(14) contains the number of forward/backward solves,
- IWORK(15) contains the total number of steps (including rejected steps),
- IWORK(16) contains the number of rejected steps due to error control,
- IWORK(17) contains the number of rejected steps due to Newton failure,
- IWORK(18) contains the number of rejected steps due to excessive growth of the solution,
- IWORK(19) contains the number of rejected steps due to IERR .EQ. -1 return of GEVAL.

The integration characteristics in IWORK(11),...,IWORK(14) refer to an implementation on a one-processor computer. When implemented on a parallel computer with four processors, one may divide these numbers by four to obtain the number of sequential evaluations, decompositions and solves.
4. Index determination

RPAR and IPAR

RPAR and IPAR are double precision and integer arrays which you can use for communication between your calling program and the subroutines GEVAL, and/or JEVAL, MEVAL. They are not altered by PSIDE. If you do not need RPAR and IPAR, ignore these parameters by treating them as dummy arguments. If you choose to use them, dimension them in GEVAL and/or JEVAL, MEVAL as arrays of appropriate length. Because of the parallel implementation of PSIDE, GEVAL must not alter RPAR and IPAR to prevent concurrent updating. JEVAL and MEVAL may alter them.

IDID

On exit:

- if IDID .EQ. 1 then the integration was successful,
- if IDID .EQ. -1 then PSIDE could not reach TEND because the stepsize became too small,
- if IDID .EQ. -2 then something else went wrong. For example this happens when the input was invalid. An error message will be printed.

4. Index determination

As mentioned before, it is important for higher-index problems to set the index of the variables in the vector IND. In this section we specify for certain problem classes, which can easily be written in the form (1.1), how this should be done. The results were taken from [HLR89]. For higher-index problems in these classes we also list the additional conditions that have to be fulfilled by the initial values. We refer to [SLV98b] for information on how PSIDE uses IND. If φ is a function of q, then we will denote the (partial) derivative of φ with respect to q by φ_q.

4.1 ODEs

First of all, Ordinary Differential Equations (ODEs), which are of the form

\[ \begin{align*}
    y' &= f(t, y), \quad y, f \in \mathbb{R}^d, \\
    t_0 &\leq t \leq t_{\text{end}}, \quad y(t_0) = y_0,
\end{align*} \]

are of index 1, i.e. we can set IWORK(2) = 0.

4.2 DAEs of index 1

The class of Differential–Algebraic Equations (DAEs) takes the form

\[ \begin{align*}
    y' &= f(t, y, z), \quad y, f \in \mathbb{R}^{d_1}, \\
    0 &= g(t, y, z), \quad z, g \in \mathbb{R}^{d_2}, \\
    t_0 &\leq t \leq t_{\text{end}}, \quad y(t_0) = y_0, \quad z(t_0) = z_0,
\end{align*} \]

where y_0 and z_0 are such that g(t_0, y_0, z_0) = 0. If g_z is invertible in the neighborhood of the solution, then (4.1) is of index 1 and IWORK(2) = 0 is the right setting.

4.3 IDEs with invertible mass matrix

Also of index 1 are problems of the form

\[ \begin{align*}
    M(y)y' &= f(t, y), \quad y, f \in \mathbb{R}^d, \\
    t_0 &\leq t \leq t_{\text{end}}, \quad y(t_0) = y_0,
\end{align*} \]

where M(y) (often called the mass matrix) is invertible in the neighborhood of the solution. Again, set IWORK(2) = 0.
4.4 DAEs of index 2

An often arising subclass of (4.1) where \(g_y\) is not invertible is

\[
\begin{align*}
y' &= f(t, y, z), \quad y, f \in \mathbb{R}^{d_1}, \\
0 &= g(t, y), \quad z, g \in \mathbb{R}^{d_2}, \\
t_0 \leq t \leq t_{\text{end}}, & \quad y(t_0) = y_0, \quad z(t_0) = z_0,
\end{align*}
\]  

(4.2)

where \(y_0\) and \(z_0\) are such that \(g(t_0, y_0) = 0\) and \(g_y(t_0, y_0)f(t_0, y_0, z_0) = 0\). If \(g_yf_z\) is invertible in the neighborhood of the solution, then (4.2) is of index 2. The variables \(y\) and \(z\) are of index 1 and 2, respectively, so set \(\text{IND}(I) = 1\) if \(I\) corresponds to a \(y\)-component, and \(\text{IND}(I) = 2\) if \(I\) corresponds to a \(z\)-component.

4.5 IDEs of index 3

If the problem is of the form

\[
\begin{align*}
y' &= f(t, y, z), \quad y, f \in \mathbb{R}^{d_1}, \\
z' &= k(t, y, z, u), \quad z, k \in \mathbb{R}^{d_2}, \\
0 &= g(t, y), \quad u, g \in \mathbb{R}^{d_3}, \\
t_0 \leq t \leq t_{\text{end}}, & \quad y(t_0) = y_0, \quad z(t_0) = z_0, \quad u(t_0) = u_0,
\end{align*}
\]

(4.3)

where \(g_yf_zk_u\) is invertible in the neighborhood of the solution and \(y_0\), \(z_0\) and \(u_0\) satisfy the conditions

\[
\begin{align*}
g(t_0, y_0) &= 0, \\
g_y(t_0, y_0)f(t_0, y_0, z_0) &= 0, \\
g_y(t_0, y_0)(f(t_0, y_0, z_0) + f_z(t_0, y_0, z_0)k(t_0, y_0, z_0)) &= 0,
\end{align*}
\]

then (4.3) is an IDE of index 3. The variables \(y\), \(z\) and \(u\) are of index 1, 2 and 3, respectively, so set \(\text{IND}(I) = 1\) if \(I\) corresponds to a \(y\)-component, \(\text{IND}(I) = 2\) if \(I\) corresponds to a \(z\)-component, and \(\text{IND}(I) = 3\) if \(I\) corresponds to a \(u\)-component.

4.6 Multibody systems of index 3

In mechanics one often encounters the problem

\[
\begin{align*}
q' &= u, \quad q, u \in \mathbb{R}^{d_4}, \\
M(q)u' &= f(t, q, u) + G^T(q)\lambda, \quad f \in \mathbb{R}^{d_2}, \\
0 &= g(t, q), \quad \lambda, g \in \mathbb{R}^{d_3}, \\
t_0 \leq t \leq t_{\text{end}}, & \quad g(t_0) = g_0, \quad u(t_0) = u_0, \quad \lambda(t_0) = \lambda_0,
\end{align*}
\]

(4.4)

where \(G(q) = g_q\), the matrix \(M(q)\) non-singular in the neighborhood of the solution and \(q_0\), \(u_0\) and \(\lambda_0\) are such that they satisfy

\[
\begin{align*}
g(t_0, q_0) &= 0, \\
G(t_0, q_0)u_0 &= 0, \\
g_q(t_0, q_0)(u_0, u_0) + G(t_0, q_0)M^{-1}(q_0)f(t_0, q_0, u_0) + G^T(q_0)\lambda_0 &= 0.
\end{align*}
\]

We could rewrite the system to the form (4.3) by premultiplying both sides of the \(u'\)-equation by \(M^{-1}(q)\). Consequently, (4.4) is of index 3 and the variables \(q\), \(u\) and \(\lambda\) are of index 1, 2 and 3, respectively, so set \(\text{IND}(I) = 1\) if \(I\) corresponds to a \(q\)-component, \(\text{IND}(I) = 2\) if \(I\) corresponds to a \(u\)-component, and \(\text{IND}(I) = 3\) if \(I\) corresponds to a \(\lambda\)-component.
5. Examples

Machine readable versions of the following two example drivers are available from [SLV98a].

5.1 Van der Pol problem

Here we give a simple example, solving the Van der Pol problem, an ODE of dimension 2.

5.1.1 Driver for Van der Pol problem

```
PROGRAM VDPOL
  C

6. **PSIDE and the ‘Test set for Initial Value Problem solvers’**

A more involved driver for PSIDE is supplied with the ‘Test set for Initial Value Problem solvers’, which is available via the World Wide Web [LS98]. This test platform not only contains the Fortran 77 routines for many test problems, but also drivers for the solvers DASSL [Pet91], MEBDFDAE [Cas98], RADAU [HW98], RADAU5 [HW96], VODE [BHB97], and PSIDE. This means that if one wants to solve a particular set of differential equations with PSIDE, it suffices to write the code that defines the problem in the test set format and link it with PSIDE and the test set driver. An additional benefit is that it is easy to compare solvers mutually. To give an impression of the performance of PSIDE in relation to that of the other solvers, we give in Figure 1–2 work-precision diagrams for two problems from [LS98]. They correspond to the Medical Akzo Nobel problem, a set of semi-discretized partial differential equations of dimension 400 which describe the injection of a medicine in a tumorous tissue, and the NAND gate, a set of 14 implicit differential equations of index 1 which model a electrical circuit performing the logical NOT(AND) operation. To produce these diagrams, we used for every solver a range of input tolerances, measured the accuracy delivered by the solver in number of correct digits and plotted these numbers against the CPU times needed for the runs on a logarithmic scale. The PSIDE-1 curves correspond to timings on a one-processor machine, the PSIDE-4 curves were obtained by dividing the one-processor timings by the speed-up factors on four processors. For an explanation how these factors were obtained, we refer to [LS98]. Results of MEBDFDAE, RADAU, RADAU5 and VODE are not included in Figure 2, because these solvers can not handle implicit differential equations directly. From Figure 1 we see that for the Medical Akzo Nobel problem PSIDE on one processor is about as efficient as DASSL, MEBDFDAE and VODE and less efficient than RADAU5, whereas PSIDE using four processors is the most efficient solver. Figure 2 reveals that for the NAND gate...

6. PSIDE and the ‘Test set for Initial Value Problem solvers’

Figure 2: Work-precision diagram for NAND gate
DASSL performs better than PSIDE in one-processor mode, but for higher tolerances worse if four processors are used. These figures are quite representative for the numerous comparisons in [LS98], which show that the speed-up factor of PSIDE with respect to the other solvers is between 1.14 and 3.28, depending on problem and solver.

Integration characteristics, complete descriptions of the test problems and the test set format, full details about the work-precision diagrams, as well as comparisons for other test problems, can be found in [LS98].

7. Installing PSIDE

7.1 Parallelism
The Fortran 77 source of PSIDE [SLV98a] contains Cray autotasking directives [Cra94]. Because of the high-level parallelism – the four stage values can be computed in parallel (cf. [SLV98b, Section 2]) – we explicitly autotask the loops that should be computed in parallel. If you are not working on a Cray, it should be almost trivial to change the given autotasking directives to facilitate your compiler. The autotasking directives appear in the source code as CMIC$ DOALL PRIVATE(VAR1,...)

SHARED(VAR1,...), beginning at column 1. The DOALL directive indicates that the DO loop that begins on the next line may be executed in parallel. PRIVATE(...) specifies that each processor will have its own private copy of these variables. SHARED(...) identifies those variables that are shared between processors.

7.2 Linear algebra
For PSIDE’s linear algebra we chose to use LAPACK. However, if you do not have available on your system both

- a machine tuned LAPACK [ABB+95], and
- a machine optimized BLAS

we suggest you use the linear algebra routines available at [SLV98a]. Of course the latter will work, however, it may give much worse performance.
