Summary
For positive recurrent nearest neighbouring, semi-homogeneous random walks on the lattice $\{0, 1, 2, \ldots\} \times \{0, 1, 2, \ldots\}$ the bivariate generating function of the stationary distribution is analysed for the case where one-step transitions to the North, North-East and East at interior points of the state space all have zero probability. It is shown that this generating function can be represented by meromorphic functions. The construction of this representation is exposed for a variety of one-step transition vectors at the boundary points of the state space.

1991 Mathematics Subject Classification: 60J15, 60K25.
Key Words & Phrases: random walks, nearest neighbouring, stationary distribution, semi-homogeneous, generating function, meromorphic functions.
Note: Part of this research is supported by the ESPRIT BRA QM IPS.

1. Introduction

Since the early seventies random walks on the lattice $\{0, 1, 2, \ldots\} \times \{0, 1, 2, \ldots\}$ have received quite some attention in the literature, this being mainly due to their use in modelling traffic flow patterns in telecommunication and computer networks. For details concerning their applications cf., e.g., Takagi [17]. For the Performance Analysis of such networks information concerning the stationary distribution of those random walks is of prime importance. Around 1980 it appeared that the determination of the stationary distribution could be formulated as a Boundary Value Problem, cf. Fayolle and Iasnogorodsky [8], Cohen and Boxma [4], Cohen [5]; for a review paper, see [6], here the problem formulation as a singular Fredholm integral is also discussed.

Nearest neighbouring random walks are a special but important subclass. From the early sixties dates a study by Groeneveld, unfortunately, it has never been published. By using uniformisation he has solved the functional equation for the "shortest queue" model and shown that the solution can be expressed in terms of elliptic functions; Malyshev's approach [14] is of a similar character. Among the nearest neighbouring models the "shortest queue" is a much studied one. Its basic analysis is due to Kingman [13] and Flatto, McKean [9]. In the context of Boundary Value Problems this model has been analysed in [8] and [4].

In a nearest neighbouring random walk the one-step transition out from an interior point $(i,j) \in \{1, 2, \ldots\} \times \{1, 2, \ldots\}$ of the state space leads with probability one to a neighbouring point $(i+h, j+k)$, $(h, k) \in \{-1, 0, 1\} \times \{-1, 0, 1\} \setminus \{(0, 0)\}$. In the shortest queue model the one-step transitions with $(h, k) \in \{(1, 1), (1, 0), (0, 1)\}$ all have probability zero. In Hofri [11] and Jaffe [12] also models with this feature are discussed almost along the same lines as in [9], and as with the "shortest queue" model the bivariate generating functions of the stationary distributions are meromorphic, i.e. their
only singularities are isolated poles. These random walks are featured by the absence of one-step transitions to the North, North-East and East, (N, NE, E) and the conjecture arises whether for such random walks the generating function of the stationary distribution, if it exists, is always meromorphic. In the present study it will be shown that under some mild conditions this conjecture is true. Questions concerning the algebraic character of the generating function have recently been also studied by Fayolle, Iaşnogorodsky, Malyshev [7]. Platto and Hahn [10] provides a model with an algebraic generating function, here the one-step transition to the North-East has a nonzero probability.

The character of the generating function of the stationary distribution of a nearest-neighbouring random walk is determined by the number of branch points of the zeros of the so-called kernel

$$p_1 p_2 - \phi_2(p_1, p_2);$$

where $\phi_2(p_1, p_2)/(p_1, p_2)$ is the bivariate generating function of the distribution of the one-step transition out from an interior point of the state space. The kernel is in general a biquadratic in $p_1$ and $p_2$, and its zeros, e.g. $p_1$ as a function of $p_2$, have generally four branching points, two in- and two outside the unit disk if the drifts $\mu_2 - 1$ and $\nu_2 - 1$ are negative, cf. (2.6). In the case with no $N$, NE and E one-step transitions there are only two finite branching points, both are inside the unit disk. The branching points inside the unit disk play an essential role in the analysis of the functional equation for the bivariate generating function at the stationary distribution. The branching points outside the unit disk play a decisive role in the analytic continuation of the bivariate generating function into the domain outside the torus generated by the two unit disks.

In the present study we consider the nearest neighbouring walk without one-step transitions to the $N$, NE and E at interior points of the state space; it is assumed that the process is positive recurrent, cf. assumption 2.1. It is shown that the generating function of the stationary distribution can be described in terms of meromorphic functions. The construction of these functions is exposed; some weak restrictions have been made, cf. assumption 4.1. Even with these restrictions quite a number of variants have to be considered.

The organisation of the present study is now described. In section 2 the model of the nearest-neighbouring random walk is defined by its one-step transition vectors at interior and at the boundary points of the state space $\{0, 1, 2, \ldots\} \times \{0, 1, 2, \ldots\}$. The random walk is semi-homogeneous, i.e. the distribution of the transition vector at interior points is independent of the position of such a point, similarly for the boundary points on the positive horizontal axis and the positive vertical axis, cf. (2.1) and (2.2). In this section the functional equation to be solved is formulated on the set of zero tuples of the kernel. By using the analytic properties of these zero tuples the functional equation is replaced by two equations with two unknown functions $\Omega_1(p), \Omega_2(p)$, defined for $|p| \leq 1$; the two branching points of a zero tuple located inside the unit disk are here instrumental, see section 3. From the structure of the coefficients in these two equations it is shown that $\Omega_1(p)$ and $\Omega_2(p)$ can be continued analytically into $|p| > 1$. In section 4 it is shown that the only singularities of these analytic continuations are poles; for the determination of the residues at these pole sets recursive linear equations are derived. The pole sets of $\Omega_1(\cdot)$ and $\Omega_2(\cdot)$ are generated by the zeros in $|p| > 1$ of some of the coefficients in the two equations for $\Omega_1(\cdot), \Omega_2(\cdot)$; the number of such zeros depends on the character of the transition vectors at the boundary points of the state space. From the results so obtained it is seen that the solution of the two functional equations for $\Omega_1(p)$ and $\Omega_2(p)$, with $\Omega_1(p), \Omega_2(p)$ both regular in $|p| < 1$ and continuous in $|p| \leq 1$ are meromorphic functions with known pole sets and recursively defined residues in $|p| > 1$. In section 5, $\Omega_1(\cdot)$, and also $\Omega_2(\cdot)$, are expressed as the sum of a polynomial and a number of meromorphic functions with given poles and residues. These meromorphic functions are, apart from a factor, explicitly known, their construction follows from the results in section 4. The polynomials and their degrees have still to be determined. Substitution of the expression for $\Omega_1(\cdot)$ and $\Omega_2(\cdot)$ into the two equations for these functions (see section 6) leads to the determination of the degrees and of the coefficients of these polynomials, and a set of linear equations for the unknown factors in the meromorphic functions remains. It is shown that the equations have a solution and so $\Omega_1(p), \Omega_2(p)$ are determined. It is finally shown that the solution so constructed leads to the unique solution of
the functional equation for the bivariate generating function of the stationary distribution. In order not to interrupt the exposition of the construction of the solution all the algebraic computations have been exposed in the appendices A, B and C.

The construction of the generating function of the stationary distribution may be also formulated as a Boundary Value problem, cf. [4], and as such it can be solved completely, also when one-step transitions to the N, NE and E occur. If they do not occur then the present approach is simpler, because it avoids the explicit calculation of a conformal mapping. In a future study the author will develop a technique for the case with N, NE and E one-step transitions which also avoids the calculation of such a mapping from an integral equation.

The present investigation has been initiated after reading the studies Adan [1]. Adan, Wessels, Zijm [2]. In his search for a direct derivation of explicit expressions for all state probabilities of the two-dimensional stationary distribution Adan starts from the equilibrium equations for these probabilities. For the general equation of this set, i.e. the equation containing no state probabilities of the boundary points of the state space, he constructs a class of solutions. By choosing suitable linear combinations of these solutions Adan tries to satisfy the boundary conditions, i.e. the equations containing boundary states. Via an iterative procedure he succeeds in constructing a sequence which, whenever it converges absolutely at all points of the state space, provides in the limit the solution of the equilibrium equations and the normal condition. This aspect of absolute convergence is actually the problem of choosing the exponents of convergence in constructing the meromorphic functions, cf. section 5 and appendix C, Adan’s approach leads to an algorithm for the numerical evaluation of the various state probabilities.

2. DESCRIPTION OF THE MODEL

We consider the two-dimensional stochastic process \( z_n, n = 0, 1, 2, \ldots \) with state space \( S \),

\[ z_n \equiv (x_n, y_n) \in S := \{0, 1, 2, \ldots \} \times \{0, 1, 2, \ldots \}. \]

For the characterisation of the structure of the \( z_n \)-process we introduce the following four sequences of stochastic vectors,

i. for every fixed \( k = 0, 1, 2, 3, \) \( (\xi_n^{(k)}, \eta_n^{(k)}), n = 0, 1, 2, \ldots, \) is a sequence of i.i.d. stochastic vectors with \( (\xi_n^{(k)}, \eta_n^{(k)}) \in S; \)

ii. the four families \( \{(\xi_n^{(k)}, \eta_n^{(k)}), n = 0, 1, 2, \ldots \} \) are independent families.

The structure of the \( z_n \)-process is defined by the following recursive relations:

i. \( z_0 \equiv (x_0, y_0) \in S \) is the starting point;

ii. \( x_{n+1} = [x_n - 1]^+ + \xi_n^{(k)} \)

\( y_{n+1} = [y_n - 1]^+ + \eta_n^{(k)} \)

with

\[ k = 3 \quad \text{for} \quad x_n > 0, \quad y_n > 0, \]
\[ = 2, \quad = 0, \quad > 0, \]
\[ = 1, \quad > 0, \quad = 0, \]
\[ = 0, \quad = 0, \quad = 0, \]

and
\[ a^+ = \max(0, 0) \text{ for } a \text{ real}. \]

We introduce the following notation and definitions

i. \( (\xi_k, \eta_k) \) shall indicate a stochastic vector with the same state space and the same distribution as \((\xi_k^{(k)}, \eta_k^{(k)})\), i.e.
\[ (\xi_k, \eta_k) \sim (\xi_k^{(k)}, \eta_k^{(k)}), \quad k = 0, 1, 2, 3; \]

ii. \[ \phi_k = \phi_k(p_1, p_2) := E\{ \xi_k, \eta_k \}, \quad |p_1| \leq 1, |p_2| \leq 1, \]
\[ \mu_k := E\{\xi_k\}, \quad \nu_k := E\{\eta_k\}. \]

From (2.1) and (2.2) it is seen that the \( \xi_n \)-process is a discrete time parameter Markov chain.

The class of nearest neighbouring random walks to be analyzed in the present study is specified by taking
\[ \phi_0(p_1, p_2) = b_{10} p_1 + b_{01} p_2 + b_{11} p_1 p_2, \quad (2.4) \]
\[ \phi_1(p_1, p_2) = h_{11} p_1^2 p_2 + h_{01} p_1 p_2 + h_{10} p_1 p_2 + h_{11} p_2^2 + h_{-1, 0}, \]
\[ \phi_2(p_1, p_2) = w_{11} p_1^2 p_2 + w_{10} p_1 p_2 + w_{01} p_1 p_2 + w_{00} p_2^2 + w_{0, -1}, \]
\[ \phi_3(p_1, p_2) = r_{-1, 1} p_2^2 + r_{-1, -1} p_1 + r_{0, -1} p_2 + r_{1, 1} p_1, \]
with
\[ \phi_k(1, 1) = 1, \quad k = 0, 1, 2, 3, \]
and all coefficients in (2.4) nonnegative.

Note that (2.2) and (2.4) imply that out from a point \((x, y)\) with \(x > 0, y > 0\), no one-step transition can occur to the North, the North-East and the East.

We introduce

**ASSUMPTION 2.1.**

i. \[ \mu_3 - 1 = r_{1, -1} - \{r_{-1, 1} + r_{-1, 0} + r_{1, -1}\} < 0, \quad (2.6) \]
\[ \nu_3 - 1 = r_{-1, 1} - \{r_{1, -1} + r_{0, -1} + r_{1, -1}\} < 0; \]

ii. \[ 0 < 4 r_{-1, 1} r_{1, -1} < 1; \]

iii. \[ \mu_1 - 1 - \nu_1 \frac{1 - \mu_3}{1 - \nu_3} < 1, \]
\[ \nu_1 - 1 - \mu_2 \frac{1 - \nu_3}{1 - \mu_3} < 1; \]

iv. \[ h_{11} + h_{01} > 0 \text{ or } w_{11} + w_{10} > 0; \]

v. \[ h_{01} > 0 \text{ whenever } h_{1k} = h_{01} = 0, \]
\[ w_{10} > 0, \quad w_{11} = w_{10} = 0. \]
Remark 2.1. Concerning (2.6)ii it is noted that $4r_{-1,1}r_{1,-1} = 1$ implies $r_{-1,1} = r_{1,-1} = \frac{1}{2}$ since $0 \leq r_{-1,1} \leq 1$, $0 \leq r_{1,-1} \leq 1$, $r_{-1,1} + r_{1,-1} \leq 1$; and so the second inequality in (2.6)ii is implied by (2.6)i. Although the case $r_{1,-1} = r_{-1,1} = \frac{1}{2}$ is an interesting case, we shall discard it because its analysis requires a slightly different approach, similarly if $r_{-1,1} = 0$ or $r_{1,-1} = 0$. The condition (2.6)iv has been introduced to guarantee that any two states of $S$ can be reached from each other with positive probability, so that the state space $S$ is irreducible. The conditions (2.6)v have been introduced to restrict the number of variants which have to be considered in the analysis, see the derivations in appendix C. However, if (2.6)v is not assumed the required analysis does not change essentially.

Whenever the conditions (2.6) hold and the state space $S$ is irreducible then the conditions (2.6)iii are necessary and sufficient for the $\mathbf{z}_n$-process to be positive recurrent, cf. Cohen [1], section II.2.6, and hence they imply that the $\mathbf{z}_n$-process possesses a unique stationary distribution. If (2.6)i is not introduced it is still possible that the $\mathbf{z}_n$-process is positive recurrent, cf. [1]; however, we shall not discuss here such cases. 

In the present study our interest concerns the study of the functional equation for the stationary distribution of the $\mathbf{z}_n$-process. To formulate this equation let

$$(x, y)$$

be a stochastic vector with distribution the stationary distribution of the $\mathbf{z}_n$-process.

Put

$$\Phi(p_1, p_2) := \mathbb{E}(P^X_1 P^Y_2), \quad |p_1| \leq 1, |p_2| \leq 1.$$ 

It is then easily derived (cf. [1], (II.4.1.3)) that:

$$(p_1 p_2 - \phi_2) \Phi(p_1, p_2)/\Phi(0, 0) = p_1 p_2 \phi_0 - \phi_2 +$$

$$(p_2 \phi_1 - \phi_3)(\frac{1}{p_1} \Omega_1(p_1) + \frac{1}{p_2} \phi_1 \phi_2 - \phi_3) p_2 \Omega_1(p_2) \text{ for } |p_1| \leq 1, |p_2| \leq 1, \quad (2.8)$$

with

$$\Omega_1(p_1) := \frac{1}{p_1} (\Phi(p_1, 0) - \Phi(0, 0))/\Phi(0, 0), \quad |p_1| \leq 1,$$

$$\Omega_2(p_2) := \frac{1}{p_2} (\Phi(0, p_1) - \Phi(0, 0))/\Phi(0, 0), \quad |p_2| \leq 1,$$

$$\phi_j \equiv \phi_j(p_1, p_2), \quad j = 0, 1, 2, 3. \quad (2.9)$$

From (2.7) and (2.9) it follows that:

$$\Omega_j(p) \text{ is regular for } |p| < 1, \quad \text{and continuous for } |p| \leq 1, \quad \text{analogously for } \Omega_j(p); 0 \leq \Omega_j(\cdot) \leq 1, \quad j = 1, 2. \quad (2.10)$$

Put

$$\omega_2(p_1, p_2) := p_2 - \phi_2(p_1, p_2),$$

$$\omega_1(p_1, p_2) := p_1 - \phi_1(p_1, p_2),$$

$$\omega_0(p_1, p_2) := 1 - \phi_0(p_1, p_2). \quad (2.11)$$

By $(\hat{p}_1, \hat{p}_2)$ we shall denote a zero tuple of the kernel

$$Z(p_1, p_2) := \phi_3(p_1, p_2) - p_1 p_2, \quad (2.12)$$
so
\[ Z(\hat{p}_1, \hat{p}_2) = 0. \]

with
\[ \hat{\omega}_j := \omega_j(\hat{p}_1, \hat{p}_2), \quad j = 0, 1, 2, \quad (2.13) \]
we obtain from (2.8), because by definition
\[ |\Omega(\hat{p}_1, \hat{p}_2)| \leq 1, \quad |\hat{p}_1| \leq 1, \quad |\hat{p}_2| \leq 1, \quad (2.14) \]
the functional equation
\[ \hat{\omega}_1 \Omega(\hat{p}_1) + \hat{\omega}_2 \Omega(\hat{p}_2) + \hat{\omega}_0 = 0, \quad (2.15) \]
and this equation applies for every zero tuple \((\hat{p}_1, \hat{p}_2)\) of \(Z(p_1, p_2)\), cf. (2.12), with \(|p_1| \leq 1, \quad |p_2| \leq 1.\)

The analysis of the functional equation (2.15) for the conditions (2.10) is the main goal of the present study.

3. On the Analysis of the Functional Equation

In this section we derive some properties concerning the solution of the functional equation (2.15) which satisfies (2.10). Zero tuples \((\hat{p}_1, \hat{p}_2)\) of the kernel \(Z(p_1, p_2)\) have been analysed in appendix A, cf. lemma A.2. For every \(\hat{p}_2\) and \(\hat{p}_1\) given by
\[ \hat{p}_1 = \frac{1}{2r_{1,-1}} \{ \hat{p}_2 - r_{0,-1} \pm (1 - 4r_{1,-1} r_{-1,1})^{1/2}(\hat{p}_2 - \delta_{21})(\hat{p}_2 - \delta_{22}) \}, \quad (3.1) \]
\((\hat{p}_1, \hat{p}_2)\) is a zero tuple of \(Z(p_1, p_2)\); here the two signs correspond with \(\hat{p}_1 = P_{12}(\hat{p}_2), \hat{p}_1 = P_{21}(\hat{p}_2)\), cf. (a.8); \(\delta_{21}, \delta_{22}\) are the branching points of \(\hat{p}_1\) as a function of \(\hat{p}_2\). Lemma A.2 states that for \(|\hat{p}_2| = 1\) the zero \(P_{12}(\hat{p}_2)\) lies in \(|p_1| \leq 1\), the other one \(P_{21}(\hat{p}_2)\) is in \(|p_1| > 1\). Note that \(-1 < \delta_{21} < \delta_{22} < 1\), cf. (a.5). Put
\[ \mathcal{G} := \{ p : \delta_{21} \leq p \leq \delta_{22} \}, \quad \mathcal{H} := \{ p : |p| \leq 1 \} \setminus \mathcal{G}, \quad (3.2) \]
and note that each of the functions in (3.1) is regular in \(\mathcal{H}\) and continuous in the closure \(\mathcal{H} \) of \(\mathcal{H}\). Note also that \(\omega_j(p_1, p_2), j = 0, 1, 2, \) cf. (2.11), are polynomials in \(p_1\) and \(p_2\), and hence \(\omega_j(\hat{p}_1, \hat{p}_2)\) is regular in \(\hat{p}_1 \in \mathcal{H}\), continuous in \(\hat{p}_2 \in \mathcal{H}\).

For \(|\hat{p}_2| = 1\) and \(\hat{p}_1 = P_{12}(\hat{p}_2), \) so \(|P_{12}(\hat{p}_2)| \leq 1, \) cf. (a.8), the functional equation (2.15) reads
\[ \hat{\omega}_1 \Omega(2)(\hat{p}_2) + \hat{\omega}_2 \Omega(1)(\hat{p}_2) + \hat{\omega}_0 = 0. \quad (3.3) \]
In (3.3) \(\hat{\omega}_j \equiv \omega_j(2)(\hat{p}_2), \omega_0(\hat{p}_2)\) and \(\Omega(1)(\hat{p}_2)\) are regular in \(\hat{p}_2 \in \mathcal{H}\), continuous in \(\hat{p}_2 \in \mathcal{H}\), cf. (2.10). Consequently it follows from (3.3) that \(\Omega(1)(\hat{p}_2)\) can be continued analytically out from \(|\hat{p}_2| = 1\) into \(\hat{p}_2 \in \mathcal{H}\), and this continuation is continuous in \(\mathcal{H}\). Because the coefficients in \(\omega_j(p_1, p_2)\) are all real, cf. (2.4) and (2.11), and the coefficients in the series expansions of \(\Omega(1)(p)\), and of \(\Omega(2)(p)\) are all nonnegative, cf. (2.9), and have a sum bounded by one, it follows that (3.3) may be rewritten as: for \(\hat{p}_2 \in \mathcal{H}\setminus \mathcal{G}\)
\[ \psi_1(\hat{p}_2) + \psi_2(\hat{p}_2) \sqrt{\hat{p}_2 - \delta_{21}}(\hat{p}_2 - \delta_{22}) = 0, \quad (3.4) \]
with \(\psi_1(\hat{p}_2), \psi_2(\hat{p}_2)\) convergent power series in \(\hat{p}_2\) with real coefficients.
For \( \tilde{p}_2 \in (\delta_{21}, \delta_{22}) \) the square root in (3.4) is purely imaginary and since for such a \( \tilde{p}_2, \psi_1(\tilde{p}_2) \) and \( \psi_2(\tilde{p}_2) \) are both real, because they are power series with real coefficients, it follows by continuity from (3.4) that
\[
\psi_1(p) = 0, \quad \psi_2(p) = 0 \quad \text{for} \quad p \in (\delta_{21}, \delta_{22}). \tag{3.5}
\]
From (3.1) it is seen that \( P_{12}(\tilde{p}_2) \) and \( P_{11}(\tilde{p}_2) \) are each other's complex conjugates for \( p_2 \in (\delta_{21}, \delta_{22}) \) and so (3.5) implies that (3.4) also holds for \( \tilde{p}_2 \in (\delta_{21}, \delta_{22}) \) with the "-" sign replaced by the "+" sign, that is we have for \( \tilde{p}_2 \in (\delta_{21}, \delta_{22}) \),
\[
\dot{\omega}_1 \Omega_1(\tilde{p}_2) + \dot{\omega}_2 \Omega_2(\tilde{p}_2) + \omega_0 = 0, \tag{3.6}
\]
with here
\[
\dot{\omega}_j = \omega_j(P_{11}(\tilde{p}_2), \tilde{p}_2), \quad j = 0, 1, 2.
\]
Using the same arguments as above it is seen that (3.6) can be continued analytically out from \( \tilde{p}_2 \in (\delta_{21}, \delta_{22}) \) into \( \mathcal{H} \). It follows that the relations (3.5) are equivalent with: for \( |p_2| \leq 1 \),
\[
\omega_1(P_{12}(p_2), p_2) \Omega_1(P_{11}(p_2)) + \omega_2(P_{12}(p_2), p_2) \Omega_2(p_2) + \omega_0(0, P_{12}(p_2), p_2) = 0, \tag{3.7}
\]
\[
\omega_1(P_{11}(p_2), p_2) \Omega_1(P_{11}(p_2)) + \omega_2(P_{11}(p_2), p_2) \Omega_2(p_2) + \omega_0(0, P_{11}(p_2), p_2) = 0. \tag{3.8}
\]
Analogously, we have, cf. remark A.1, for \( |p_1| \leq 1 \),
\[
\omega_1(p_1, P_{21}(p_1)) \Omega_1(p_1) + \omega_2(p_1, P_{21}(p_1)) \Omega_2(P_{21}(p_1)) + \omega_0(0, p_1, P_{21}(p_1)) = 0, \tag{3.9}
\]
\[
\omega_1(p_1, P_{22}(p_1)) \Omega_1(p_1) + \omega_2(p_1, P_{22}(p_1)) \Omega_2(P_{22}(p_1)) + \omega_0(0, p_1, P_{22}(p_1)) = 0. \tag{3.10}
\]
Because \( \omega_j(p_1, p_2), \quad j = 0, 1, 2, \) are polynomials in \( p_1 \) and \( p_2 \), and \( P_{12}(p) \) and \( P_1(p) \) are regular in the entire finite \( p \)-plane slitted along \( \mathcal{G} \), it is seen that all the coefficients in (3.7) and (3.8) are regular in this slitted \( p \)-plane. From lemma A.2 we have \( P_{11}(1) > 1 \) and since all coefficients in (3.8) are real for \( p_2 = 1 \) and \( \Omega_1(p) \) is a power series in \( p \) with nonnegative coefficients it follows that \( \Omega_1(p) \) has an analytic continuation in \( |p_1| < P_{11}(1) \). Analogously, \( \Omega_2(p_2) \) has such a continuation in \( |p_2| < P_{21}(1) \), cf. (a.11), and \( \Omega_1(P_{11}(1)), \Omega_2(P_{21}(1)) \), are both finite. So the relations (3.7) and (3.8) hold for \( |p_2| \leq P_{21}(1) \), and (3.9) and (3.10) hold for \( |p_1| \leq P_{11}(1) \), i.e. the domain of validity of (3.7) and (3.8) has been extended by analytic continuation, similarly for (3.9) and (3.10). Actually, the relations (3.7) and (3.8) are linear in \( \Omega_1(\cdot), \Omega_2(\cdot) \), and their coefficients are all regular in the \( p_2 \)-plane slitted along \( \mathcal{G} \), and so by analytic continuation it is seen as above that \( \Omega_1(p) \) and \( \Omega_2(p) \) possess analytic continuations for \( |p| > 1 \), except possibly at those points \( p \) where the coefficients of \( \Omega_2(p) \) in (3.7) and \( \Omega_1(p) \) in (3.10) are zero, at such points \( \dot{\omega}_1(\cdot) \) and/or \( \dot{\omega}_2(\cdot) \) may have poles, and these poles may generate via (3.8) and (3.10) other poles, see section 4. Branching points cannot occur, since \( P_{12}(p), P_{11}(p) \), are regular in the slitted \( p \)-plane and the relations (3.7) and (3.8) are linear in \( \Omega_1(\cdot) \) and \( \Omega_2(\cdot) \). Consequently, it follows that \( \Omega_1(p) \) and \( \Omega_2(p) \) which are regular for \( |p| < 1 \), cf. (2.10), are meromorphic functions for \( |p| \geq 1 \), if their singularities, i.e. their poles, do not have a finite accumulation point, and this is actually the case, as will be shown, cf. (c.2) of appendix C and (6.5). Note that a function is a meromorphic function if it is regular in the finite complex plane except for at most a finite number of singularities in every bounded domain, these singularities being simple or multiple poles.

**Remark 3.1.** Because the \( z_n \)-process is positive recurrent and the state space \( S \) is irreducible cf. remark 2.1, \( \Omega_1(p) \) and \( \Omega_2(p) \) cannot be polynomials. \( \square \)

**Remark 3.2.** From the derivations above it is readily seen that the set of relations (3.7) and (3.8) is
4. On the Determination of the Poles and Residues.

In the proceeding section it has been shown that \(\Omega_1(p)\) and \(\Omega_2(p)\) should be meromorphic functions with poles located in \(|p| > 1\), cf. (2.10). In this section we shall discuss the location of these poles and derive relations for the residues at these poles.

Because \(\Omega_1(p)\) and \(\Omega_2(p)\) are meromorphic and the coefficients in (3.7) and (3.8) are regular for \(|p| \geq 1\), the principle of permanence, cf. [3], p.106, implies that (3.7) and (3.8) hold for \(|p| \geq 1\); i.e. for \(|p| \geq 1\),

\[
\omega_1(\Omega_1(\Omega_2(p)) + \omega_2(\Omega_2(p), p)\Omega_2(p) + \omega_0(P_{12}(p), p) = 0, \tag{4.1}
\]

\[
\omega_1(\Omega_1(p), p)\Omega_1(\Omega_1(p)) + \omega_2(\Omega_1(p), p)\Omega_2(p) + \omega_0(P_{11}(p), p) = 0. \tag{4.2}
\]

For the present we consider the case, cf. (2.6)iv,

\[
w_{11} + w_{01} > 0, \tag{4.3}
\]

the discussion of the other case of (2.6)iv, is similar. Hence lemma B.1.ii guarantees the existence of a zero \(\sigma^{(1)}\) such that

\[
\omega_2(P_{22}(\sigma^{(1)}), \sigma^{(1)}) = 0, \quad |\sigma^{(1)}| > 1. \tag{4.4}
\]

This zero \(\sigma^{(1)}\) generates recursively the two sequences, cf. remarks A.2 and A.3,

\[
\{\sigma^{(i)}, i = 1, 2, \ldots\} \quad \text{and} \quad \{\tau^{(i)}, i = 1, 2, \ldots\}, \tag{4.5}
\]

with

\[
\tau^{(i)} := P_{11}(\sigma^{(i)}) \quad \text{and} \quad \sigma^{(i+1)} := P_{21}(\tau^{(i)}).
\]

From (a.8),(a.11) and remarks A.2 and A.3, it is seen that

\[
1 < |\sigma^{(1)}| < |\tau^{(1)}| < |\sigma^{(2)}| < \ldots < |\sigma^{(i)}| < |\tau^{(i+1)}| < |\sigma^{(i+1)}| < \ldots, \tag{4.6}
\]

\[
\sigma^{(i)} = P_{22}(\tau^{(i)}), \quad \tau^{(i)} = P_{12}(\sigma^{(i+1)}),
\]

\(\sigma^{(i)}\) and \(\tau^{(i)}\) are all positive or are all negatives.

Put

\[
A_2(p) := \omega_1(P_{12}(p), p)\Omega_1(P_{12}(p)) + \omega_0(P_{12}(p), p), \tag{4.7}
\]

and suppose for the present (cf. remarks 4.1 and 6.5 below) that

\[
0 \neq |A_2(\sigma^{(1)})| < \infty. \tag{4.8}
\]

It then follows from (4.1) and (4.8) since \(\sigma^{(1)}\) is a simply zero, cf. (4.4) and lemma B.1.ii, that

\[
p = \sigma^{(1)} \text{ is a simple pole of } \Omega_2(p). \tag{4.9}
\]

Consequently, if

\[
\omega_1(P_{11}(p), p) \neq 0 \quad \text{for} \quad p = \sigma^{(1)}, \tag{4.10}
\]
then (4.2) implies that
\[ p = \tau^{(1)} = P_{11}(\sigma^{(1)}) \text{ is a simple pole of } \Omega_1(p). \]  

(4.11)

If, however
\[ \omega_1(P_{11}(\sigma^{(1)}, \sigma^{(1)})) = \omega_1(\tau^{(1)}, P_{22}(\tau^{(1)})) = 0, \]

(4.12)

then \( p = \tau^{(1)} \) is a pole with multiplicity two of \( \Omega_1(p) \).

Suppose that (4.10) holds and that
\[ \omega_1(P_{12}(p), p) \neq 0 \quad \text{for} \quad p = \sigma^{(2)}, \]

(4.13)

then, cf. (4.1),
\[ \Omega_2(p) \text{ has a simple pole at } p = \sigma^{(2)}, \]

(4.14)

since
\[ \omega_2(P_{12}(\sigma^{(2)}), \sigma^{(2)}) \neq 0. \]

(4.15)

This relation (4.15) holds, because (4.3) and lemma B.1.ii imply that \( \omega_2(P_{12}(p), p) \) has only one zero in \(|p| > 1\) if \( \omega_{11} = 0 \), whereas if \( \omega_{11} > 0 \) it has two such zeros but with different signs and this contradicts (4.8).

If
\[ \omega_1(P_{12}(\sigma^{(2)}), \sigma^{(2)}) = 0, \]

(4.16)

then
\[ \Omega_2(p) \text{ has no pole at } p = \sigma^{(2)}. \]

(4.17)

It is seen that if \( \Omega_2(p) \) has a pole at \( \sigma^{(2)} \) then starting from (4.11) with \( p = \sigma^{(2)} \) instead of \( p = \sigma^{(1)} \) analogous conclusions follow. So by starting with \( \sigma^{(1)} \) it is seen that \( \sigma^{(1)} \) may generate pole sequences of \( \Omega_1(p) \) and \( \Omega_2(p) \), however, we have to consider in more detail (4.8), (4.10) and (4.13). See the following remark.

Remark 4.1. As exposed in remark A.3 we may complete the sequences (4.5) by \( \tau^{(0)}, \sigma^{(0)}, \tau^{(-1)}, \sigma^{(-1)}, \ldots \), so that
\[ |\tau^{(-n)}| < 1 < |\sigma^{(-n+1)}| < \ldots < |\tau^{(-1)}| < |\sigma^{(0)}| < |\tau^{(0)}| < |\sigma^{(1)}| < |\tau^{(1)}| < \ldots, \]

(4.18)

with \( n \) finite, supposing that a \( \tau \)-element is the first one which becomes in absolute value less than one, if it is a \( \tau \)-element only minor changes are needed in the following considerations.

If \( n = 0 \) so that
\[ \Omega_1(P_{12}(\sigma^{(1)})) = \Omega_1(\tau^{(0)}), \quad |\tau^{(0)}| < 1, \]

then, cf. (2.10), \( |\Omega_1(\tau^{(0)})| < 1 \), i.e. \( A_2(\sigma^{(1)}) \) is finite, and so \( \Omega_2(p_2) \) has a simple pole at \( p_2 = \sigma^{(1)} \) if \( A_2(\sigma^{(1)}) \neq 0 \); otherwise, if \( A_2(\sigma^{(1)}) = 0 \), \( \sigma^{(1)} \) does not generate a pole of \( \Omega_2(p) \).

If \( n > 1 \) then consider (4.1) for \( p = \sigma^{(0)}, \ldots, \sigma^{(-n+1)} \). Whenever for all those \( p \) the coefficients in (4.1)
\[ \omega_1(P_{12}(p), p) \neq 0, \]

(4.19)
then \( \Omega_1(p_1(p_2)) \) and \( \Omega_2(p_2) \) have no poles for those \( p \) and so \( A_2(\sigma^{(1)}) \) is finite; note that \( \omega_2(P_{12}(p), p) \neq 0 \) for those \( p \), cf. the proof of (4.15).

Further if

\[
\omega_1(P_{12}(p), p) \neq 0 \quad \text{for all } p = \sigma^{(i+1)}, \quad i = 1, 2, \ldots, \quad (4.20)
\]

then, since \( \omega_2(P_{12}(p), p) \neq 0 \) for \( p = \sigma^{(i+1)} \), \( i = 1, 2, \ldots \), cf. (4.15), it follows from (4.1) that if \( A_2(\sigma^{(1)}) = 0 \) then all \( \Omega_1(p_1(p_2)) \) and all \( \Omega_2(p_2) \) are finite for \( p = \sigma^{(i+1)}, \quad i = 1, 2, \ldots \), and so \( \sigma^{(1)} \) does not generate pole sequences for \( \Omega_1(p) \) and \( \Omega_2(p) \). Concerning \( A_2(\sigma^{(1)}) \neq 0 \), see, remark 6.5 below.

The analysis in the following sections will be based on

**Assumption 4.1.** For \( i = -n + 1, -n + 2, \ldots, 0, 1, 2, \ldots \), cf. (4.5) and (4.18), it is supposed that

i. \( \omega_1(\tau^{(i)}, P_{22}(\tau^{(i)}))) \equiv \omega_1(P_{11}(\sigma^{(i)}), \sigma^{(i)}) \neq 0, \quad (4.21) \)

ii. \( \omega_1(\tau^{(i)}, P_{21}(\tau^{(i)}))) \equiv \omega_1(P_{12}(\sigma^{(i+1)}), \sigma^{(i+1)}) \neq 0. \)

**Remark 4.2.** It is readily seen that (4.21)i excludes the case that poles with multiplicity larger than one do occur, cf. (4.12), whereas (4.21)ii disregards the case with a finite number of poles generated by \( \sigma^{(1)} \), cf. (4.16). From the definition of the \( \sigma^{(1)} \) and \( \tau^{(i)} \) it is readily seen that in general assumption 4.1 will apply.

From the discussion above it follows for the case (4.3) if \( A(\sigma_i) \neq 0 \), cf. (4.7) and remark 4.1, that

\[
\Omega_2(p) \quad \text{has a simple pole at } p = \sigma^{(i)}, \quad \text{cf. (4.9)}, \\
\Omega_1(p) \quad \text{for } i = 1, 2, \ldots, \quad (4.22)
\]

and, generally,

\[
\Omega_2(p) \quad \text{has a simple pole at } p = \sigma^{(i)}, \quad i = 1, 2, \ldots, \\
\Omega_1(p) \quad \text{for } i = 1, 2, \ldots, \quad (4.22)
\]

assumption 4.1 excludes the case of poles with multiplicity larger than one.

Next we start with the determination of the residues at the various poles. Put, for \( i = 1, 2, \ldots \),

\[
R_1(\tau^{(i)}) := \lim_{p \to \tau^{(i)}} (p - \tau^{(i)}) \Omega_1(p), \quad (4.23)
\]

\[
R_2(\sigma^{(i)}) := \lim_{p \to \sigma^{(i)}} (p - \sigma^{(i)}) \Omega_2(p).
\]

It follows from (4.1) with \( A_2(\sigma^{(1)}) \neq 0 \), note that \( A_2(\sigma^{(1)}) < \infty \), cf. remark 4.1, that since \( \sigma^{(1)} \) is a simple pole of \( \Omega_2(p) \),

\[
R_2(\sigma^{(1)}) = A_2(\sigma^{(1)}) \left[ \frac{d}{dp} \omega_2(P_{12}(p), p) \right]_{p=\sigma^{(1)}}^{-1}.
\]

Further from (4.2),

\[
\Omega_1(P_{11}(p)) = \frac{\omega_2(P_{11}(p), p)}{\omega_1(P_{11}(p), p)} \Omega_2(p) - \frac{\omega_0(P_{11}(p), p)}{\omega_1(P_{11}(p), p)},
\]

and so
\[ R_1(\sigma^{(1)}) = -\left\{ \frac{\omega_2(P_{11}(p), p)}{\omega_1(P_{11}(p), p)} \right\} \frac{d}{dp} P_{11}(p) \right\}_{p = \sigma^{(1)}} R_2(\sigma^{(1)}). \]  
(4.25)

Analogously, it follows from (4.1),

\[ R_2(\sigma^{(2)}) = -\left\{ \frac{\omega_1(P_{12}(p), p)}{\omega_2(P_{12}(p), p)} \right\} \frac{d}{dp} P_{12}(p) \right\}_{p = \sigma^{(2)}} R_1(\sigma^{(1)}). \]  
(4.26)

Generally, we have for \( i = 1, 2, \ldots, \)

\[ R_1(\sigma^{(i)}) = -\left\{ \frac{\omega_2(P_{11}(p), p)}{\omega_1(P_{11}(p), p)} \right\} \frac{d}{dp} P_{11}(p) \right\}_{p = \sigma^{(i)}} R_2(\sigma^{(i)}), \]  
(4.27)

\[ R_2(\sigma^{(i+1)}) = -\left\{ \frac{\omega_1(P_{12}(p), p)}{\omega_2(P_{12}(p), p)} \right\} \frac{d}{dp} P_{12}(p) \right\}_{p = \sigma^{(i+1)}} R_1(\sigma^{(i)}). \]

**Remark 4.3.** Because \( P_{12}(p) \) and \( P_{11}(p) \) are for \( |p| > 1 \) regular functions of \( p \) it is seen from (4.5) that the derivatives in (4.26) and (4.27) are all nonzero and finite.

5. **Definition of Meromorphic Functions**

Let \( \sigma \) with \( |\sigma| > 1 \) be a zero of

\[ \omega_2(P_{12}(\sigma), p), \]  
(5.1)

assuming that such a zero exists, cf. lemma B.1. Denote by \( S_2(\sigma) \) the sequence

\[ S_2(\sigma) := \{ \sigma^{(1)}, \tau^{(1)}, \sigma^{(2)}, \tau^{(2)}, \ldots \}, \]  
(5.2)

with, cf. (4.5),

\[ \sigma^{(1)} = \sigma, \tau^{(i)} := P_{11}(\sigma^{(i)}), \quad \sigma^{(i+1)} := P_{21}(\tau^{(i)}), \quad i = 1, 2, \ldots. \]  
(5.3)

Analogously, with \( \tau, |\tau| > 1 \), a zero of

\[ \omega_1(p, P_{22}(p)), \]  
(5.4)

we define the sequence

\[ S_1(\tau) := \{ \tau^{(1)}, \sigma^{(1)}, \tau^{(2)}, \sigma^{(2)}, \ldots \}, \]  
(5.5)

with

\[ \tau^{(1)} = \tau, \sigma^{(i)} := P_{21}(\tau^{(i)}), \quad \tau^{(i+1)} := P_{11}(\sigma^{(i)}), \quad i = 1, 2, \ldots. \]  
(5.6)

The sequence \( S_2(\sigma) \) generates the meromorphic functions

\[ M_2(p|\sigma) := \sum_{i=1}^{\infty} \frac{R_{2e}(\sigma^{(i)})}{p - \sigma^{(i)}} \left[ \frac{p}{\sigma^{(i)}} \right]^{m_2}, \]  
(5.7)

\[ M_1(p|\sigma) := \sum_{i=1}^{\infty} \frac{R_{1e}(\tau^{(i)})}{p - \tau^{(i)}} \left[ \frac{p}{\tau^{(i)}} \right]^{m_1}, \]  
(5.8)

where \( R_{2e}(\sigma^{(i)}) \) and \( R_{1e}(\tau^{(i)}) \) are defined as \( R_2(\sigma^{(i)}) \) and \( R_1(\tau^{(i)}) \) in (4.27), the index \( \sigma \) has been
incorporated in the notation to indicate that the series in (5.7) and (5.8) are generated by the sequence $S_2(\sigma)$, cf. (5.2);

\begin{equation}
(5.9)
\end{equation}

ii. $m_{2\pi}$ and $m_{1\pi}$ are the smallest nonnegative integers for which series

\begin{equation}
(5.10)
\end{equation}

converge absolutely.

Because of (c.2), (c.3) and the existence of the limits in (c.11) and (c.12) it is readily seen that $m_{2\pi}$ and $m_{1\pi}$ are always well defined for the sequence $S_2(\sigma)$, for details see remark 6.1 below.

Analogously, the sequence $S_1(\tau)$, cf. (5.5), generates the meromorphic functions

\begin{equation}
(5.11)
\end{equation}

\begin{equation}
(5.12)
\end{equation}

(note that here the $\tau^{(i)}$ and $\sigma^{(i)}$ are different from those in (5.7), (5.8).

The functions in (5.7), (5.8), (5.11) and (5.12) are well defined in the sense that they converge uniformly and absolutely in every finite circle $|p| \leq R$, with $R > 1$, whenever the terms with poles inside the circle with radius $R$ are deleted from the sum, cf. [2], p. 309, [6], p. 219.

In appendix C it is shown, cf. (c.18), that

\begin{equation}
(5.13)
\end{equation}

and so we can delete the indices "2" and "1" and hence define

\begin{equation}
(5.14)
\end{equation}

6. SOLUTION OF THE FUNCTIONAL EQUATION

In this section we shall construct the solution of the functional equation (2.15), i.e. we shall show how $\Omega_1(\tau)$ and $\Omega_2(\tau)$ are to be determined.

From lemma B.1 it is seen that $\omega_2(P_2(p), p)$ has at most two zeros, say, $\sigma_{12}$ and $\sigma_{22}$ in $|p| > 1$, and, similarly, $\omega_1(p, P_2(p))$ has at most two zeros, say, $\tau_{12}$ and $\tau_{12}$ in $|p| > 1$. Assumption (2.6)iv guarantees that at least one of these possible four zeros exists. In the subsequent analysis we shall always use these four zeros, if, however, a zero does not exist then all symbols referring to that nonexistent zero should be deleted from the text, cf. remark (6.4) below.

From the present it will be assumed that

\begin{equation}
(6.1)
\end{equation}

cf. (4.8) and remark 4.1, with

\begin{equation}
(6.2)
\end{equation}

**Remark 6.1.** For the relevant alterations to be made in the subsequent analysis if (6.1) does not hold, see remark 6.5, below.
Each of the zeros $\sigma_{21}$ and $\sigma_{22}$ generates a sequence of the type as defined in (5.2), and similarly do the zeros $\tau_{11}$ and $\tau_{12}$, cf. (3.5). Denote these sequences by

$$S_{2}(\sigma_{21}), S_{2}(\sigma_{22}) \quad \text{and} \quad S_{1}(\tau_{11}), S_{2}(\tau_{12});$$

(6.3)

and (4.21) is assumed to apply for the elements of $S_{1}(\sigma_{21})$ and those of $S_{2}(\sigma_{22})$ and the analogous assumption is made for the elements of $S_{1}(\tau_{11})$, as well as for those of $S_{1}(\tau_{12})$.

For each of these four sequences we construct a pair of meromorphic functions, cf. (5.7) and (5.8) for $\sigma_{21}$ and $\sigma_{22}$, and (5.11) and (5.12) for $\tau_{11}$ and $\tau_{12}$; note that here (6.1) is used, cf. remark 4.1. These pairs of meromorphic functions are denoted by

$$\{M_{2}(p|\sigma_{21}), M_{1}(p|\sigma_{21})\}, \quad \{M_{2}(p|\sigma_{22}), M_{1}(p|\sigma_{22})\},$$

(6.4)

$$\{M_{1}(p|\tau_{11}), M_{2}(p|\tau_{11})\}, \quad \{M_{1}(p|\tau_{12}), M_{2}(p|\tau_{12})\}.$$

Put

$$\Omega_{2}(p) := Q_{2}(p) + M_{2}(p),$$

$$\Omega_{1}(p) := Q_{1}(p) + M_{1}(p),$$

(6.5)

where

i. $M_{2}(p) := M_{2}(p|\sigma_{21}) + M_{2}(p|\sigma_{22}) + M_{2}(p|\tau_{11}) + M_{2}(p|\tau_{12}),$

(6.6)

$$M_{1}(p) := M_{1}(p|\sigma_{21}) + M_{1}(p|\sigma_{22}) + M_{1}(p|\tau_{11}) + M_{1}(p|\tau_{12});$$

ii. $Q_{2}(p)$ and $Q_{1}(p)$ are both polynomials in $p$ of degree $n_{2}$ and $n_{1}$ respectively, these degrees will be specified below.

Substitution of (6.5) into the functional equations (4.1) and (4.2) yields: for $|p| \geq 1$,

$$\omega_{1}(P_{12}(p),p)Q_{1}(P_{12}(p)) + \omega_{2}(P_{12}(p),p)Q_{2}(p) + \omega_{0}(P_{12}(p),p) = I_{12}(p),$$

(6.7)

$$\omega_{1}(P_{11}(p),p)Q_{1}(P_{11}(p)) + \omega_{2}(P_{11}(p),p)Q_{2}(p) + \omega_{0}(P_{11}(p),p) = I_{11}(p),$$

where

$$-I_{12}(p) := \omega_{1}(P_{12}(p),p)M_{1}(P_{12}(p)) + \omega_{2}(P_{12}(p),p)M_{2}(p),$$

(6.8)

$$-I_{11}(p) := \omega_{1}(P_{11}(p),p)M_{1}(P_{11}(p)) + \omega_{2}(P_{11}(p),p)M_{2}(p).$$

**REMARK 6.2.** Consider one of the sequences in (6.3), say $S_{2}(\sigma_{21})$ and put

$$\tau_{0} := P_{12}(\sigma_{21}^{(1)}) \quad \text{with} \quad \sigma_{21}^{(1)} = \sigma_{21},$$

(6.9)

$$\tau_{i} := \tau_{21}^{(1)} \quad \sigma_{i} := \sigma_{21}^{(1)}, \quad i = 1, 2, \ldots.$$

It then follows from (6.7) for $i = 1, 2, \ldots$,

$$\omega_{1}(\tau_{i-1},\sigma_{i})Q_{1}(\tau_{i-1}) + \omega_{2}(\tau_{i-1},\sigma_{i})Q_{2}(\sigma_{i}) + \omega_{0}(\tau_{i-1},\sigma_{i}) = I_{12}(\sigma_{i}),$$

(6.10)

$$\omega_{1}(\tau_{i},\sigma_{i})Q_{1}(\tau_{i}) + \omega_{2}(\tau_{i},\sigma_{i})Q_{2}(\sigma_{i}) + \omega_{0}(\tau_{i},\sigma_{i}) = I_{11}(\sigma_{i}),$$
which represents a set of linear (recursive) equations for the elements of the sequences

\[ \{Q_1(\tau_i), \ i = 0, 1, \ldots \} \quad \text{and} \quad \{Q_2(\sigma_i), \ i = 1, 2, \ldots \}. \] 

(6.11)

It is seen that these sequences are uniquely determined when \( I_{12}(\tau_1), I_{11}(\tau_1) \) and \( Q_2(\sigma_1) \) are known.

\[ \square \]

Put, cf. (2.4),

\[ s_1 := 3 \quad \text{for} \quad h_{11} > 0, \]

\[ := 2 , , \quad = 0 \quad h_{01} + h_{10} > 0, \]

\[ := 1 , , \quad = 0, \quad = 0; \] 

(6.12)

\[ s_2 := 3 \quad \text{for} \quad w_{11} > 0, \]

\[ := 2 , , \quad = 0 \quad w_{10} + w_{01} > 0, \]

\[ := 1 , , \quad = 0, \quad = 0; \]

\[ s_0 := 2 \quad \text{for} \quad b_{11} > 0, \]

\[ = 1 , , \quad = 0. \]

It is then readily seen that the following limits exist, cf. (2.4), (2.6), (2.11) and lemma A.3, and are finite,

\[ \delta_{0,12} := \lim_{p \to -\infty} p^{-s_0} \omega_0(P_{12}(p), p), \quad \delta_{0,11} := \lim_{p \to -\infty} p^{-s_0} \omega_0(P_{11}(p), p), \]

(6.13)

\[ \delta_{1,12} := \lim_{p \to -\infty} p^{-s_1} \omega_1(P_{12}(p), p), \quad \delta_{1,11} := \lim_{p \to -\infty} p^{-s_1} \omega_1(P_{11}(p), p), \]

\[ \delta_{2,12} := \lim_{p \to -\infty} p^{-s_2} \omega_1(P_{12}(p), p), \quad \delta_{2,11} := \lim_{p \to -\infty} p^{-s_2} \omega_2(P_{11}(p), p), \]

and their values are finite and nonzero, except possibly for \( s_1 = 1 \) and \( s_2 = 1 \) where they may be zero in special cases, note that (2.6)iv excludes \( s_1 = s_2 = 1 \).

Again we consider the sequence \( S_2(\sigma_{21}) \) and with the abbreviated notation introduced in (6.9) put, cf. (5.9) and (5.14),

\[ R_1(\cdot) := R_{1\sigma_{21}}(\cdot), \quad R_2(\cdot) := R_{2\sigma_{21}}(\cdot), \]

(6.14)

\[ m := m_{\sigma_{21}}, \]

and
\[ -I_{12}^{(i)}(p|\sigma_2) := \omega_1(P_{12}(p),p)\frac{R_1(\sigma_i)}{p^m} \left( \frac{p}{p - \sigma_i} \right)^m, \quad \text{for } i = 1, \]
\[ := \omega_1(P_{12}(p),p)\frac{R_1(\tau_{i-1})}{P_{12}(p) - \tau_{i-1}} \left( \frac{P_{12}(p)}{P_{12}(p) - \tau_{i-1}} \right)^m + \]
\[ \omega_2(P_{12}(p),p)\frac{R_2(\sigma_i)}{p^m} \left( \frac{p}{p - \sigma_i} \right)^m, \quad \text{for } i = 2, 3, \ldots; \] (6.15)
\[ -I_{11}^{(i)}(p|\sigma_2) := \omega_1(P_{11}(p),p)\frac{R_1(\tau_i)}{P_{11}(p) - \tau_i} \left( \frac{P_{11}(p)}{P_{11}(p) - \tau_i} \right)^m + \]
\[ \omega_2(P_{11}(p),p)\frac{R_2(\sigma_i)}{p^m} \left( \frac{p}{p - \sigma_i} \right)^m \quad \text{for } i = 1, 2, \ldots. \]

Further we introduce
\[ -I_2(p|\sigma_2) := -\sum_{i=1}^{\infty} I_{12}^{(i)}(p|\sigma_2) = \]
\[ = \omega_1(P_{12}(p),p)M_1(P_{12}(p)|\sigma_2) + \omega_2(P_{12}(p),p)M_2(P_{12}(p)|\sigma_2), \] (6.16)
\[ -I_1(p|\sigma_2) := -\sum_{i=1}^{\infty} I_{11}^{(i)}(p|\sigma_2) = \]
\[ = \omega_1(P_{11}(p),p)M_1(P_{11}(p)|\sigma_2) + \omega_2(P_{11}(p),p)M_2(P_{11}(p)|\sigma_2). \]

The form (6.15) may be rewritten as:

i. \[ I_{12}^{(i)}(p|\sigma_2) = \left\{ \frac{\omega_1(P_{12}(p),p)}{p^m} \frac{R_1(\tau_{i-1})}{P_{12}(p) - \tau_{i-1}} \left( \frac{P_{12}(p)}{P_{12}(p) - \tau_{i-1}} \right)^m \right\} \frac{p - \sigma_i}{p^m} p^{m+s_i}, \] (6.17)
\[ + \frac{\omega_2(P_{12}(p),p)}{p^m} \frac{R_2(\sigma_i)}{\sigma_i^m} p^{m+s_i}, \quad i = 2, 3, \ldots; \]

ii. \[ I_{11}^{(i)}(p|\sigma_2) = \left\{ \frac{\omega_1(P_{11}(p),p)}{p^m} \frac{R_1(\tau_i)}{P_{11}(p) - \tau_i} \left( \frac{P_{11}(p)}{P_{11}(p) - \tau_i} \right)^m \right\} \frac{p - \sigma_i}{p^m} p^{m+s_i}, \]
\[ + \frac{\omega_2(P_{11}(p),p)}{p^m} \frac{R_2(\sigma_i)}{\sigma_i^m} p^{m+s_i}, \quad i = 1, 2, \ldots, \]

iii. \[ I_{12}^{(i)}(p|\sigma_2) = -\frac{R_2(\sigma_i)}{\sigma_i^m} \frac{\omega_2(P_{12}(p),p)}{(p - \sigma_i)^{p^m}} p^{m+s_i}. \]

Consider the term between parantheses in the first relation of (6.17). Because \( P_{12}(p) \) is regular for \( |p| > 1 \) this term is here also regular, note \( \tau_{i-1} = P_{12}(\sigma_i) \). Consider the series expansion of this term in a neighbourhood of \( \sigma_i \) note \( |\sigma_i| > 1 \). The second relation of (4.27) has actually been obtained from (4.1) by multiplying (4.1) by \( p - \sigma_i \) and then letting \( p \to \sigma_i \). Hence the second relation of (4.27) implies that this series expansion should contain the factor \( p - \sigma_i \), i.e. \( p = \sigma_i \) is a zero of the term inside parantheses of (5.17). Hence, by using assumption 4.1, lemma A.3 and (6.13), it follows that the following limit exists and
\[ 0 < \lim_{p \to \infty} p^{-m} \left| I_{12}^{(i)}(p|\sigma_2) \right| < \infty, \quad i = 2, 3, \ldots, \] (6.18)
with, cf. (6.14),
\[ n_{\sigma_{21}} := \max(m + s_1 - 1, m + s_2 - 1). \]  

(6.19)

Similarly, from (6.17)ii and iii,

\[ 0 < \lim_{p \to \infty} p^{-n_{\sigma_{21}}} I_{12}^{(i)}(p|\sigma_{21}) < \infty, \quad i = 1, 2, \ldots, \]  

(6.20)

\[ 0 < \lim_{p \to \infty} p^{-(m+s_2-1)} I_{12}^{(i)}(p|\sigma_{21}) < \infty. \]

Note that the existence of the zero \( \sigma_{21} \) implies that \( s_2 \geq 2 \), cf. (6.13) and lemma B.1. It further follows that the functions defined in (6.15) are regular for all finite \( p \) with \( |p| > 1 \), so that the definition of \( m \), cf. (6.14), implies for every finite \( R > 1 \), cf. (6.16),

\[ p^{-n_{\sigma_{21}}} I_{12}(p|\sigma_{21}) = -p^{-n_{\sigma_{21}}} \lim_{N \to \infty} \sum_{i=1}^{N} I_{12}^{(i)}(p|\sigma_{21}), \quad |p| < R, \]  

(6.21)

where the sum in (6.21) converges absolutely and uniformly in \( p \) for \( 1 < |p| < R \), to a finite limit for \( N \to \infty \), which is uniformly bounded for \( |p| < R \), cf. the discussion in appendix C below (c.13). Analogously for \( I_{11}(p|\sigma_{21}) \). Consequently,

\[ I_{12}(p|\sigma_{21}) \text{ has a pole of order } n_{\sigma_{21}} \text{ at infinitely } (p = \infty), \text{ similarly for } I_{11}(p|\sigma_{21}). \]  

(6.22)

**Lemma 6.1.** \( I_{12}(p|\sigma_{21}) \) and \( I_{11}(p|\sigma_{21}) \) are polynomials of degree \( n_{\sigma_{21}} \).

**Proof.** From the conclusions concerning the sum in (6.21) and the regularity of its terms it is seen that \( I_{12}(p|\sigma_{21}) \) is regular for finite \( p \) and hence from (6.22) and Liouville's theorem it follows that \( I_{12}(p|\sigma_{21}) \) is a polynomial of degree \( n_{\sigma_{21}} \), analogously for \( I_{11}(p|\sigma_{21}) \). \( \square \)

A similar analysis as that leading to (6.22) for the sequence \( S_2(\sigma_{21}) \) leads to analogous results for the other sequences in (6.3). Put

i. \[ n_u := \max(m_u + s_1 - 1, m_u + s_2 - 1 | u \in (\sigma_{21}, \sigma_{22}, \gamma_{11}, \gamma_{12})]. \]  

(6.23)

ii. \[ n(s_1, s_2) := \max(n_{\sigma_{21}}, n_{\sigma_{22}}, n_{\gamma_{11}}, n_{\gamma_{12}}, s_0), \]

the index \( u \) being that one for which the max occurs in i. Further, cf. (6.6), (6.12), (6.16), (6.22),

\[ \gamma_{12} := \lim_{p \to \infty} p^{-n(s_1,s_1)}[\omega_1(P_{12}(p), p) M_1(P_{12}(p)) + \omega_2(P_{12}(p), p) M_2(p) + \omega_0(P_{12}(p), p)], \]  

(6.24)

\[ \gamma_{11} := \lim_{p \to \infty} p^{-n(s_1,s_1)}[\omega_1(P_{11}(p), p) M_1(P_{11}(p)) + \omega_2(P_{11}(p), p) M_2(p) + \omega_0(P_{11}(p), p)], \]  

(6.25)

note that these limits are finite and that (6.23) implies

\[ n(s_1, s_2) \geq s_j \geq 1, \quad j = 1, 2, 3. \]  

(6.26)

Hence we obtain from the functional equations (6.7) by using (6.15), (6.24), (6.25) and (6.26); for \( |p| \to \infty \),

\[ \delta_{1,12} Q_1(\alpha_{12} p) p^{s_1} + \delta_{2,11} Q_2(p) p^{s_2} = \gamma_{12} p^{n(s_1,s_1)} + O(p^{n(s_1,s_1)-1}), \]  

(6.27)

\[ \delta_{1,11} Q_1(\alpha_{11} p) p^{s_1} + \delta_{2,11} Q_2(p) p^{s_2} = \gamma_{11} p^{n(s_1,s_1)} + O(p^{n(s_1,s_1)-1}). \]

Note that (2.6)iv excludes the case \( s_1 = s_2 = 1 \), cf. (6.12).
From (6.26) and (6.27) it follows that the degrees \( n_2 \) and \( n_1 \) of the polynomials \( Q_2(p) \) and \( Q_1(p) \), cf. (6.6)ii, are determined by
\[
\begin{align*}
n_2 &= n(s_1, s_2) - s_2, \\
n_1 &= n(s_1, s_2) - s_1.
\end{align*}
\] (6.28)

**Remark 6.3.** In remark C.2 it has been pointed out that if in (c.21) \( m \) is replaced by \( m + h \), \( h = 1, 2, \ldots \), then the convergence is maintained; and so in the definitions (5.7) and (5.8) we may also take as exponents \( m_\sigma + h \) with \( h \) a nonnegative integer. In doing so it is readily seen that the degrees of \( Q_2 \) and \( Q_1 \) then become larger. Such a change in exponents in (5.7) and (5.8) implies that in the representation (6.5) a polynomial is subtracted from \( M_2(p) \) and added to \( Q_2(p) \).

The relations (5.7), (5.8), (5.11) together with (6.5) and (6.6) characterise the structure of the functions \( \Omega_1(p) \) and \( \Omega_2(p) \); they also determine these functions uniquely, as it will be shown below.

Because the degrees of the polynomials \( Q_2(\cdot) \) and \( Q_1(\cdot) \) have been determined we need for the explicit determination of the coefficients of these polynomials in total \( n_1 + n_2 + 2 \) linear equations.

In remark 6.2 it has been shown, by using the sequence \( S_2(\sigma_{21}) \) which generates the pole sets of the meromorphic functions \( M_2(p|\sigma_{21}), M_1(p|\sigma_{21}) \), that the values of the polynomial \( Q_1(p) \) at the \( r \)-points and those of \( Q_2(p) \) at the \( \sigma \)-points of the sequence \( S_2(\sigma_{21}) \) can be expressed as linear combinations of \( I_{12}(\sigma) \) and \( I_{11}(\sigma) \) at the \( \sigma \)-points of \( S_2(\sigma_{21}) \). In total we need only \( n_1 + n_2 + 2 \) of those relations. So \( Q_2(\cdot) \) and \( Q_1(\cdot) \) are known, whenever \( I_{12}(p) \) and \( I_{11}(p) \) are known, see remark 6.5 below for their uniqueness. To show that these functions are completely determined note that a pair of meromorphic functions \( \{M_2(p|\sigma_{21}), M_1(p|\sigma_{21})\} \), cf. (5.7), (5.8), is determined by \( S_2(\sigma_{21}) \) apart from a factor, because all residues \( R_{2\sigma_{21}}(\cdot) \) of \( M_2(p|\sigma_{21}) \) and those of \( M_1(p|\sigma_{21}) \) at their poles are linear functions of \( R_{2\sigma_{21}}(\sigma_{21}^{(1)}) \) with \( \sigma_{21}^{(1)} = \sigma_{21} \), cf. (4.24) and (4.27); actually they are all proportional to \( R_{3\sigma_{21}}(\sigma_{21}^{(1)}) \).

By using the expression (4.24) for the residue \( R_{3\sigma_{21}}(\sigma_{21}^{(1)}) \) it is seen that \( M_2(p|\sigma_{21}) \) and \( M_1(p|\sigma_{21}) \) are completely determined apart from a factor which is a linear function of \( \Omega_1(P_{12}(\sigma_{21}^{(1)})) \), supposing that \( A_2(\sigma_{21}^{(1)}) \neq 0 \), cf. Remark 4.1 and Remark 6.5 below. If \( A_2(\sigma_{21}^{(1)}) = 0 \) then \( S_2(\sigma_{21}) \) does not generate a pole set. Similarly, for the other pairs of meromorphic functions in (6.4), i.e. it remains to determine
\[
\begin{align*}
\Omega_1(p) & \text{ for } p = P_{12}(\sigma_{21}^{(1)}) \text{ and } p = P_{12}(\sigma_{22}^{(1)}), \\
\Omega_2(p) & \text{ for } p = P_{22}(\delta_{11}^{(1)}) \text{ and } p = P_{22}(\delta_{12}^{(1)}).
\end{align*}
\] (6.29)

Hence by using (6.7) and (6.8) four linear equations are obtained for the unknowns
\[
\begin{align*}
\Omega_1(P_{23}(\sigma_{21}^{(1)})), \quad \Omega_1(P_{12}(\sigma_{22}^{(1)})), \quad \Omega_2(P_{21}(\delta_{11}^{(1)})), \quad \Omega_2(P_{22}(\delta_{12}^{(1)})),
\end{align*}
\] (6.30)
since as shown above the coefficients in the polynomials \( Q_2(p) \) and \( Q_1(p) \) depend linearly on the unknowns in (6.30).

**Remark 6.4.** It has been mentioned already in the beginning of the present section that if \( \omega_1(P_{12}(p), p) \) and \( \omega_1(p, P_{22}(p)) \) do not have in total four zeros in \( |p| > 1 \) but less, then only the sequences generated by the existing zeros do occur, as do the functions derived from these sequences. It is then readily seen that for the number of remaining unknowns we are left with a same number of linear equations, whenever the corresponding terms in (6.1) are nonzero, cf. Remark 6.5 below.

For the ultimate determination of \( \Omega(p_1, p_2), \) cf. (2.7) and (2.8), it remains to determine \( \Omega(0, 0) \) since \( \Omega_1(p) \) and \( \Omega_2(p) \) have been constructed above. By taking \( p_2 = 1 \) in (2.8), dividing the resulting expression by \( p_1 - 1 \), note that all coefficients in (2.8) are zero for \( p_1 = p_2 = 1 \), we obtain for \( p_2 \to 1 \) a linear relation for \( \Omega(0, 0) \) because the normal condition requires \( \Phi(1, 1) = 1; \Phi(0, 0) \) so calculated is unique and positive, see the following remark.
REMARK 6.5. Apart from assumption 4.1, which has been introduced for technical reasons, cf. remark 4.2, our analysis is essentially based on assumption 2.1. The conditions (2.6), iii guarantee that the $\pi_n$-process has a unique stationary distribution and so $\Omega(p_1, p_2)$ should be regular for $|p_1| < 1$, continuous for $|p_1| \leq 1$ for every fixed $p_2$ with $|p_2| \leq 1$; and, similarly, with $p_1$ and $p_2$ interchanged. It is seen that $\Omega_1(p)$ and $\Omega_2(p)$ as defined in (6.5) satisfy the conditions (2.10), independently of the values of the unknowns in (6.30). The relations (4.1) and (4.2), or equivalently (6.5), stem from the requirement that zeros of the kernel $Z(p_1, p_2)$ at $|p_1| \leq 1, |p_2| \leq 1$, should be zeros of the right-hand side of (2.8), because of the boundedness of $\Phi(p_1, p_2)$ in $p_1 \leq 1, |p_2| \leq 1$. From these relations and the regularity properties of $\Omega_3(p)$ and $\Omega_4(p)$, a set of linear equations for the coefficients in the polynomials $Q_3(p)$ and $Q_4(p)$ and the unknowns in (6.30) has been obtained, the number of unknowns and that of the equations being equal, independently of the number of zeros of $\omega_2(P_{12}(p), p)$ and of $\omega_1(p, P_{22}(p))$ in $|p| > 1$, cf. remark 6.4, but there is at least one such a zero, because of (6.6)iv, see lemma B.1. Because there is a unique $\Omega(p_1, p_2)$ satisfying (2.8) and the mentioned regularity conditions; the set of linear equations, just mentioned, should have a unique solution and the same holds for the determination of $\Phi(0, 0)$, cf. remark 6.4. This uniqueness of $\Omega(p_1, p_2)$ leads also to the conclusion that at least one of the inequalities in (6.1) should apply for the zeros of $\omega_2(P_{12}(p), p)$ of $\omega_1(p, P_{22}(p))$ in $|p| > 1$. If it turns out that for such a zero the relevant inequality in (6.1) does not hold then this zero does not generate a pole set $S(\cdot)$, cf. (6.3), and the inherent functions $M_2(p\cdot), M_1(p\cdot)$ are identically zero. Actually the conditions in (6.1) can be only verified if the relevant unknowns in (6.30) have been solved from the linear equations, on the other hand it is evident from the analysis above that only incidentally one or more of the conditions in (6.1) are not satisfied.

ACKNOWLEDGEMENT. The author is grateful to Mr. S.C. Borst for his very useful comments.

APPENDIX A. ON THE ZEROS OF THE KERNEL

For the analysis of the functional equation (2.15) we need several properties of the zero tuples of the kernel (2.12), these properties will be derived in this appendix.

From (2.4), (2.5) and (2.12) we have

$$Z(p_1, p_2) = \phi_3(p_1, p_2) - p_1 p_2$$

$$= r_{-1,1} p_2^2 + r_{-1,0} p_2 + r_{-1,-1} + r_{0,-1} p_1 + r_{1,-1} p_1^2 - p_1 p_2. \tag{a.1}$$

Generally, a zero tuple of $Z(p_1, p_2)$ will be indicated by $(\dot{p}_1, \dot{p}_2)$. It is readily verified that, cf. also (2.6),

$$\dot{p}_1 = 1 \Rightarrow \dot{p}_2 = 1 \text{ or } \dot{p}_2 = 1 + \frac{1 - \mu_2}{r_{-1,1}} > 0, \tag{a.2}$$

$$\dot{p}_1 = 1 \Rightarrow \dot{p}_1 = 1 \text{ or } \dot{p}_1 = 1 + \frac{1 - \mu_3}{r_{1,-1}} > 0.$$

Denote by $D_2(p_2)$ the discriminant of the right-hand side of (a.1), considered as a quadratic in $p_1$,

$$D_2(p_2) = (1 - 4r_{-1,-1} r_{-1,1}) p_2^2 - 2p_2 (r_{0,-1} + 2r_{-1,-1} r_{-1,0}) - 4r_{-1,-1} r_{-1,-1} + r_{0,-1}^2$$

$$= (1 - 4r_{-1,-1} r_{-1,1}) (p_2 - \delta_{21}) (p_2 - \delta_{22}), \tag{a.3}$$

with

$$\delta_{21}, \delta_{22} \text{ the two zeros of } D_2(p_2), \ |\delta_{21}| = |\delta_{22}|. \tag{a.4}$$
Lemma A.1.

\(-1 < \delta_{21} < \delta_{22} < 1.\) (a.5)

Proof. From (a.3) we have

\(D_3(\frac{1}{q}) = \frac{1}{q^2} \{(1-r_{0,1}q)^2 - 4r_{1,-1}(r_{-1,1} + r_{-1,1}q + r_{-1,-1}q^2)\}.\) (a.6)

Obviously, (a.2) implies that

\(D_3(1) > 0.\) (a.7)

It is seen that \(q^2D_3(1/q)\) decreases on \([0,1],\) and

\[q^2D_3(\frac{1}{q}) > q^2D_3(\frac{1}{q'}) \quad \text{for} \quad q \in [0,1],\]

so \(D_3(p_2)\) has no zero for \(p_2^{-1} = q \in [-1,1].\) Because \(D_3(r_{0,-1}) < 0\) it follows, cf. (a.7), that \(D_3(\frac{1}{q})\) has two real zeros and so (a.5) follows.

□

Lemma A.2. The two zeros \(P_{11}(p_2), P_{12}(p_2)\) of \(Z(p_1, p_2)\) may be defined so that

\(|P_{12}(p)| < |p| < |P_{11}| \quad \text{for} \quad |p| \geq 1, \quad p \neq 1,\) (a.8)

\(P_{12}(1) = 1 < P_{11}(1) = 1 + \frac{1 - \mu_3}{r_{1,-1}},\)

and \(P_{11}(p), P_{12}(p)\) are both regular functions of \(p\) for \(|p| \geq 1\) and can be continued analytically out from \(|p| = 1\) into \(\{p : |p| < 1, p \notin (\delta_{21}, \delta_{22})\}.\)

Proof. Put \(p_1 = x p_2\) then \(Z(p_1, p_2) = 0\) implies, cf. (a.1),

\[z = E\{x^s p_2^{-\xi_3 + \eta_3 - 2}\}.\] (a.9)

From (2.4) it follows that \(\xi_3 + \eta_3 \leq 2,\) and (2.6)i, ii, imply

\[\Pr(\xi_3 + \eta_3 = 2) = r_{-1,1} + r_{1,-1} < 1.\]

Hence for \(|p_2| > 1, p_2 \neq 1, |z| = 1,\)

\[|E\{x^s p_2^{-\xi_3 + \eta_3 - 2}\}| < 1.\] (a.10)

Because both sides of (a.9) are regular functions of \(z\) for \(|z| \leq 1,\) Rouché's theorem, cf. [16], p. 155, shows that (a.9) has a unique zero in \(|z| < 1\) for \(|p_2| \geq 1, p_2 \neq 1.\) For \(p_2 = 1,\) (a.9) has one root in \(|z| \leq 1,\) viz. \(z = 1,\) cf. (a.2). From (a.1) it is seen that (a.9) is a quadratic equation in \(z.\) Since for \(|p_2| \geq 1\) it has exactly one root in \(|z| \leq 1,\) the other root is in \(|z| > 1.\) Take \(P_{12}(p_2)\) for \(p_2 \geq 1\) as the zero of \(Z(p_1, p_2)\) which corresponds to the zero in \(|z| \leq 1\) and \(P_{11}(p_2)\) as the zero corresponding to \(|z| > 1,\) then the relation (a.8) follow. Lemma A.1 implies that the branching points \(\delta_{21}\) and \(\delta_{22}\) of \(P_{11}(p_2)\) and \(P_{12}(p_2)\) are located in \((-1, 1),\) and so the zero \(P_{11}(p_2)\) and \(P_{12}(p_2)\) are both regular in \(|p_2| \geq 1.\) Since \(\delta_{21}\) and \(\delta_{22}\) are their only branching points, (a.5) implies that they can be continued analytically into \(\{p : |p| < 1, p \notin (\delta_{21}, \delta_{22})\}.\)
REMARK A.1. The analogous lemma for $Z(p_1, p_2)$ can be formulated for its zeros as a function of $p_1$ with $|p_1| > 1$. So for $|p_1| > 1$ we designate these zeros by $P_{21}(p_1)$ and $P_{22}(p_1)$ and such that

$$|P_{21}(p_1)| > |p_1| > |P_{22}(p_1)|, |p_1| > 1.$$  \[\text{(a.11)}\]

REMARK A.2. Take $|p_2^{(1)}| > 1$ and put

$$p_1^{(1)} := P_{11}(p_2^{(1)}), \quad p_2^{(2)} := P_{21}(p_1^{(1)}), \quad p_1^{(2)} := P_{12}(p_2^{(2)}), \quad p_2^{(3)} := P_{21}(p_1^{(2)}),$$

then from (a.8) and (a.11),

$$p_2^{(1)} = P_{22}(p_1^{(1)}), \quad p_1^{(1)} = P_{12}(p_2^{(2)}).$$

These mappings are illustrated in the figure below.

\[\text{Figure}\]

for real $p_2^{(1)} > 1$. From lemma A.2 and remark A.1 it follows that

$$1 < |p_2^{(1)}| < |p_1^{(1)}| < |p_2^{(2)}| < |p_1^{(2)}| < \ldots.$$  \[\text{(a.12)}\]

LEMA A.3. The following limits exist and

$$\alpha_{12} := \lim_{p_1 \to \infty} \frac{P_{12}(p_2)}{p_2} = \frac{1}{2r_{1,-1}} \left(1 - (1 - 4r_{1,-1}r_{-1,1})^{\frac{1}{2}} \right) > 0;$$  \[\text{(a.13)}\]

$$\alpha_{11} := \lim_{p_1 \to \infty} \frac{P_{11}(p_2)}{p_2} = \frac{1}{2r_{1,-1}} \left(1 + (1 - 4r_{1,-1}r_{-1,1})^{\frac{1}{2}} \right) > 0;$$

$$\alpha_{21} := \lim_{p_1 \to \infty} \frac{P_{21}(p_1)}{p_1} = \frac{1}{2r_{-1,1}} \left(1 + (1 - 4r_{1,-1}r_{-1,1})^{\frac{1}{2}} \right) > 0;$$

$$\alpha_{22} := \lim_{p_1 \to \infty} \frac{P_{22}(p_1)}{p_1} = \frac{1}{2r_{-1,1}} \left(1 - (1 - 4r_{1,-1}r_{-1,1})^{\frac{1}{2}} \right) > 0.$$

PROOF. From (a.1) we have

$$\hat{p}_1 = \frac{1}{2r_{1,-1}} \left(\hat{p}_2 - r_0, -1 \pm (1 - 4r_{-1,1}r_{1,-1})^{\frac{1}{2}} \sqrt{(\hat{p}_2 - \delta_{21})(\hat{p}_2 - \delta_{22})}\right),$$

and from this relation together with (2.6)ii, (a.8) and (a.11) the relations (a.13) follow. \[\square\]

REMARK A.3. It is readily verified by using (2.6)ii that in the $(p_1, p_2)$-plane the curve $Z(p_1, p_2) = 0$, $p_1$ and $p_2$ both real, represents a hyperbola. Its center is in the first quadrant and its asymptotic directions are given by $p_1 = \alpha_{11}p_2$ and $p_1 = \alpha_{12}p_2$, cf. (a.13). From lemma A.1 it is seen that the two branches of the hyperbola are located inside the acute angles between the asymptotes, note $\alpha_{11} > 0,$ $\alpha_{12} > 0.$
To $p_2^{(1)}$ in (a.12) corresponds a zero

$$p_1^{(0)} := P_{12}(p_2^{(1)}), \quad |p_1^{(0)}| < |p_2^{(1)}|.$$  \hspace{1cm} (a.14)

as it follows from lemma A.2. If $|p_1^{(0)}| > 1$ then we can again apply this lemma and define

$$p_2^{(0)} := P_{22}(p_1^{(0)}), \quad |p_2^{(0)}| < |p_1^{(0)}|.$$  

If $|p_2^{(0)}| > 1$ then again using the lemma we may define

$$p_2^{(-1)} := P_{12}(p_2^{(0)}),$$

and so on. So we may continue the sequence in (a.12) to the left, i.e. by elements which decrease in absolute value. From the location of the hyperbola just described and by using (a.5) it is seen that this completion of the sequence in (a.12) stops after a finite number of steps, because one of the $p_i^{(n)}$, $p_2^{(1)}$, $i = 0, -1, -2, \ldots$, will be in absolute value less than or equal to one.

It is finally noted that the iterated zeros of $Z(p_1, p_2)$ in remark A.2 are all real if $p_2^{(1)}$ is real, and they all refer to the same branch of the hyperbola $Z(p_1, p_2) = 0$. Since these branches one is located in the first quadrant, the other in the third quadrant, cf. (a.5), it is seen that in a sequence of iterated zeros these zeros all have the same sign and do not have a finite point of accumulation. \hfill \Box

**APPENDIX B. ON THE ZEROS OF $\omega_2(P_{12}(p), p)$**

For the detailed analysis of the relations (4.1) and (4.2) we need information concerning the zeros of some of its coefficients. Put, cf. (2.11)

$$f_2(p) := \omega_2(P_{12}(p), p) \equiv p - \phi_2(P_{12}(p), p),$$  \hspace{1cm} (b.1)

hence for $p \neq 0$,

$$p^{-3} f_2(p) = \frac{1}{p^2} - E\{(P_{12}(p), \xi, \eta, \eta^{-3})\}.  \hspace{1cm} (b.2)$$

For the investigation of the number of zeros of $f_2(p)$ in $|p| < 1$ and $|p| > 1$ we have to distinguish several cases.

i. The case $w_{11} > 0$.

It is seen from (2.2) and (2.4) that

$$\xi_2 + \eta_2 - 3 \leq 0 \quad \text{and} \quad \Pr\{\xi_2 + \eta_2 = 3\} = w_{11} > 0.  \hspace{1cm} (b.3)$$

Put for $|t| < 1$,

$$p^{-3} f_2(t, p) := \frac{1}{p^2} - tE\{(P_{12}(p), \xi, \eta, \eta^{-3})\}.  \hspace{1cm} (b.4)$$

Because $P_{12}(p)$ is a regular function of $p$ for $|p| \geq 1$ and $|P_{12}(p)/p| \leq 1$ for $|p| \geq 1$, cf. lemma A.2, it follows that for $|t| < 1$, $|p| \geq 1$, cf. (b.3),

$$|tE\{(P_{12}(p), \xi, \eta, \eta^{-3})\}| < 1,$$

and so by applying Roaché’s theorem, cf. [15], it is seen that $f_2(t, p)$ has for $|t| < 1$ two zeros in
\[ |p| > 1. \] These zeros are obviously continuous functions of \( t \) and both have a limit for \( t \to 1 \). Denote these limiting values by, say, \( \sigma_{21} \) and \( \sigma_{22} \), then

\[ |\sigma_{21}| \geq 1, \quad |\sigma_{22}| \geq 1. \] (b.5)

From (b.3) and lemma A 3 it is readily verified that

\[ \lim_{p \to \infty} E\{(\frac{P_{12}(p)}{p})\xi_p \xi_{3-p} \eta_{1-p}\} = E\{\sigma_{12}^2 (\xi_2 + \eta_1 = 3)\} > 0; \] (b.6)

so that, since the expectation in (b.4) is equal to one for \( p = 1 \) it is easily seen that the zeros of (b.4) in \( |p| > 1 \) are both real for real \( t \) with \( |t| < 1 \). Hence, \( \sigma_{21} \) and \( \sigma_{22} \) are then both real; one, say, \( \sigma_{21} \), is negative, the other is positive, so

\[ \sigma_{21} \leq -1, \quad \sigma_{22} \geq 1. \] (b.7)

Obviously, \( p = 1 \) is a zero of \( f_2(p) \). To investigate whether \( \sigma_{22} > 1 \) or \( \sigma_{22} = 1 \) we consider the derivatives with respect to \( p^{-1} \) of both terms in the right-hand side of (b.2). So

\[ \frac{d}{du} E\{(\frac{P_{12}(u^{-1})}{u^{-3}})\xi_{3-u} \eta_{1-u}\}\bigg|_{u=1} = 3 - \nu_2 - \mu_2 \frac{d}{dp} P_{12}(p)\bigg|_{p=1}. \] (b.8)

By definition of \( P_{12}(p) \) we have

\[ P_{12}(p) = E\{(\frac{P_{12}(p)}{p})\xi_p \eta_p\}, \]

and it follows that, cf. (2.5)i,

\[ \frac{dP_{12}(p)}{dp}\bigg|_{p=1} = \frac{1 - \nu_2}{1 - \mu_2}, \] (b.9)

so by using (2.6)iii,

\[ \frac{d}{du} E\{(\frac{P_{12}(u^{-1})}{u^{-3}})\xi_{3-u} \eta_{1-u}\}\bigg|_{u=1} = 2 - (\nu_2 - 1 - \mu_2 \frac{1 - \nu_2}{1 - \mu_2}) > 2. \] (b.10)

Hence by replacing in (b.2) \( p \) by \( u^{-1} \) it is easily seen that at \( u = 1 \) the slope of \( \xi^2 \) is less than that of \( E\{(\frac{P_{12}(u^{-1})}{u^{-3}})\xi_{3-u} \eta_{1-u}\} \), and hence, if \( w_{11} > 0 \), then \( f_2(p) \) has in \( |p| \geq 1 \) three zeros, viz. one at \( p_2 = 1 \) and two in \( p > 1 \), i.e. \( \sigma_{21} < -1, \sigma_{22} > 1 \).

Elimination of \( p_1 \) from \( \omega_1(p_1, p) = 0 \) and \( \omega_2(p_1, p) = 0 \) leads to an algebraic equation of the sixth degree (note (2.6)iii) and so this equation has six zeros. It has been shown above that exactly three of these zeros are located in \( |p| \leq 1 \), one at \( p = 1 \), the other two in \( |p| > 1 \), and as it is readily seen these zeros in \( |p| \geq 1 \) all have multiplicity one. Hence of the six zeros three are located in \( |p| < 1 \).

ii. The case \( w_{11} = 0, w_{10} + w_{01} > 0 \).

From (b.1) we have

\[ p^{-2} f_2(p) = \frac{1}{p} - E\{(\frac{P_{12}(p)}{p})\xi_p \xi_{3-p} \eta_{1-p}-2\}, \] (b.11)

and, cf. (2.2) and (2.4),

\[ w_{11} = 0, \quad w_{10} + w_{01} > 0 \Rightarrow \xi_2 + \eta_2 - 2 \leq 0, \quad P_r(\xi_2 + \eta_2 = 2) = w_{10} + w_{01} > 0. \] (b.12)
An analysis completely analogous with that of case i above shows that $f_2(p)$ has exactly two zeros in $|p| \geq 1$, one at $p = 1$, the other is positive both have multiplicity one. For the present case elimination of $p_1$ from $\omega_1(p_1, p) = 0$, $\omega_2(p_1, p) = 0$, yields an algebraic equation of the fourth degree, and so $f_2(p)$ has exactly two zeros in $|p| < 1$.

Finally, we consider

iii. The case $w_{11} = w_{10} = w_{01} = 0$, $w_{1,-1} > 0$, $w_{0,-1} > 0$.

From (b.1) we have

$$p^{-1} f_2(p) = 1 - \mathbb{E}\left\{ \frac{P_{12}(p)}{p} \right\} \xi_1 p \xi_4 + \eta_2^{-1},$$

and, cf. (2.2) and (2.4),

$$w_{11} + w_{01} + w_{10} = 0, w_{1,-1} > 0, w_{0,-1} > 0 \Rightarrow \xi_2 + \eta_2 \leq 1, \Pr\{\xi_2 + \eta_2 = 1\} = w_{1,-1} > 0.$$  \hspace{1cm} (b.14)

As above it is shown for the present case that $f_2(p)$ has in $|p| \geq 1$ exactly one zero, viz. $p = 1$, its multiplicity is one. Because now $f_2(p) = 0$ is equivalent with an algebraic equation of the third degree, it has exactly two zeros in $|p| < 1$.

The analysis above leads to the following lemma, cf. also Adan [1], p. 48.

**Lemma B.1.** The function $\omega_2(P_{12}(p), p)$ has at $p = 1$ a zero with multiplicity one (note (2.6)i) and:

i. if $w_{11} > 0$ it has three zeros in $|p| < 1$ and two zeros in $|p| \geq 1$, $p \neq 1$, one is negative, the other is positive;

ii. if $w_{11} = 0$, $w_{10} + w_{01} > 0$, it has one zero in $|p| \geq 1$, $p \neq 1$, which is positive and has multiplicity one, and in $|p| < 1$ it has two zeros;

iii. if $w_{11} = w_{10} = w_{01} = 0$, $w_{1,-1} > 0$, $w_{0,-1} > 0$ it has no zeros in $|p| \geq 1$, $p \neq 1$, and two zeros in $|p| < 1$;

iv. if $p_2$ with $|p_2| \geq 1$ is a zero of $\omega_2(P_{12}(p), p)$ then $\omega_2(P_{11}(p), p) \neq 0$.

**Proof.** The statements i, ii, iii have been proved above. The fourth statement follows from (2.4), (2.11) and lemma A.2. \hfill \square

**Remark B.1.** For the function $\omega_1(p, P_{22}(p))$ the lemma analogous with lemma B.1 may be proved, its formulation and proof are similar, so they are omitted. \hfill \square

**Appendix C. Asymptotics of $R_1(\tau^{(i)}), R_2(\sigma^{(i)})$ for $i \to \infty$**

In this section we derive the asymptotic behaviour: for $i \to \infty$ of the residues $R_1(\tau^{(i)})$ and $R_2(\sigma^{(i)})$, cf. (4.27).

We start with the asymptotic behaviour of $\sigma^{(i)}$ and $\tau^{(i)}$ for $i \to \infty$, cf. (4.5). From (2.6)i it is seen that $p_1$ as a function of $p_2$, with $\phi_2(p_1, p_2) - p_1 p_2 = 0$, represents a hyperbola, cf. also remark A.3, with asymptotic directions given by, cf. (a.13),

$$p_1 = \alpha_1 p_2 \quad \text{and} \quad p_1 = \alpha_1 p_2;$$  \hspace{1cm} (c.1)

and so using (4.5), (a.8) and (a.11) it is readily seen that

$$\lim_{i \to \infty} |\sigma^{(i)}| = \infty, \quad \lim_{i \to \infty} |\tau^{(i)}| = \infty,$$  \hspace{1cm} (c.2)

hence the sequences $\{\sigma^{(i)}, i = 1, 2, \ldots\}$ and $\{\tau^{(i)}, i = 1, 2, \ldots\}$, do not have a finite accumulation point.
From lemma A.3 and (4.5) it follows that
\[
\lim_{i \to \infty} \frac{\tau^{(i)}}{\sigma^{(i)}} = \alpha_{11} > 1, \quad \lim_{i \to \infty} \frac{\tau^{(i)}}{\sigma^{(i+1)}} = \alpha_{12} < 1,
\]
(c.3)
from which it follows readily that
\[
\lim_{i \to \infty} \frac{\sigma^{(i+1)}}{\sigma^{(i)}} = \frac{\alpha_{11}}{\alpha_{12}} = \lim_{i \to \infty} \frac{\tau^{(i+1)}}{\tau^{(i)}} > 1.
\]
(c.4)
Next we consider
\[
\frac{\omega_2(P_{11}(\sigma^{(5)}), \sigma^{(i)})}{\omega_1(P_{11}(\sigma^{(5)}), \sigma^{(i)})} = \frac{\omega_2(\tau^{(i)}, \sigma^{(i)})}{\omega_1(\tau^{(i)}, \sigma^{(i)})} = \frac{w_{11}p_2 + w_{10} - \frac{1}{P_1} + w_{1,-1} \frac{1}{P_2} + \frac{w_{0,1}}{P_1} + \frac{w_{0,-1}}{P_1\bar{P}_2}}{h_{11}p_1 + h_{01} - \frac{1}{P_2} + h_{-1,1} \frac{1}{P_1} + \frac{h_{0,-1}}{P_2} + h_{-1,0} \frac{1}{P_1\bar{P}_2}}
\]
\[p_1 = \tau^{(i)}, \quad p_2 = \sigma^{(i)}
\]
(c.5)
It follows from (2.6)iv, v, (c.2) and (c.5) that: for \(i \to \infty\),
\[
\frac{\omega_2(\tau^{(i)}, \sigma^{(i)})}{\omega_1(\tau^{(i)}, \sigma^{(i)})} = \frac{1}{\alpha_{11}} \frac{w_{11}}{h_{11}} (1 + O\left(\frac{1}{\tau^{(i)}}\right))
\]
for \(w_{11} > 0, h_{11} > 0\),
\[
= \frac{1}{\tau^{(i)}} \frac{1}{h_{11}} \{w_{10} + w_{01} \frac{1}{\alpha_{11}}\} (1 + O\left(\frac{1}{\tau^{(i)}}\right)) \quad \Rightarrow \quad w_{11} = 0, h_{11} > 0,
\]
\[
= \sigma^{(i)} \frac{w_{11}}{h_{01} + h_{10} \alpha_{11}} (1 + O\left(\frac{1}{\sigma^{(i)}}\right)) \quad \Rightarrow \quad w_{11} > 0, h_{11} = 0,
\]
\[
= \frac{w_{12} + w_{01} \frac{1}{\alpha_{11}}}{h_{01} + h_{10} \alpha_{11}} (1 + O\left(\frac{1}{\sigma^{(i)}}\right)) \quad \Rightarrow \quad w_{11} = 0, h_{11} = 0.
\]
(c.6)
Similarly, we obtain for \(i \to \infty\),
\[
\frac{\omega_1(P_{12}(\sigma^{(i)}), \sigma^{(i)})}{\omega_2(P_{12}(\sigma^{(i)}), \sigma^{(i)})} = \frac{\omega_1(\tau^{(i-1)}, \sigma^{(i)})}{\omega_2(\tau^{(i-1)}, \sigma^{(i)})} = \frac{h_{11}}{w_{11}} (1 + O\left(\frac{1}{\sigma^{(i)}}\right))
\]
for \(w_{11} > 0, h_{11} > 0\),
\[
= \tau^{(i-1)} \frac{1}{h_{11}} \{w_{10} + w_{01} \frac{1}{\alpha_{12}}\} (1 + O\left(\frac{1}{\sigma^{(i)}}\right)) \quad \Rightarrow \quad w_{11} = 0, h_{11} > 0,
\]
\[
= \frac{1}{\sigma^{(i)}} \frac{1}{w_{11}} \{h_{01} + h_{10} \alpha_{12}\} (1 + O\left(\frac{1}{\sigma^{(i)}}\right)) \quad \Rightarrow \quad w_{11} > 0, h_{11} = 0,
\]
\[
= \frac{h_{01} + h_{10} \alpha_{12}}{w_{10} + w_{01} \frac{1}{\alpha_{12}}} (1 + O\left(\frac{1}{\sigma^{(i)}}\right)) \quad \Rightarrow \quad w_{11} = 0, h_{11} = 0.
\]
(c.7)
For \(p_1, p_2\) satisfying \(Z(p_1, p_2) = 0\), i.e. cf. (2.12),
\[
r_{-1,1}p_2^3 - p_1p_2 + r_{1,-1}p_1^2 + r_{-1}p_2 + r_{0,-1}p_1 + r_{-1,-1} = 0,
\]
we have
\[
\frac{dp_1}{dp_2} = \frac{-p_1}{p_2} \left( 1 - 2r_{-1,-1}p_5/p_1 - r_{-1}/p_2 \right)
\]
\[
(c.8)
\]

With \( p_1 = P_{11}(p_2) \), and \( p_1 = P_{12}(p_2) \), \( |p_2| > 1 \), we obtain from lemma A.3, with some algebra,

\[
\lim_{p \to \infty} \frac{dp_{11}(p)}{dp} = \alpha_{11}, \quad \lim_{p \to \infty} \frac{dp_{12}(p)}{dp} = \alpha_{12}.
\]
\[
(c.9)
\]

From (4.27) we have

\[
\frac{R_2(\sigma^{(1)})}{R_2(\sigma^{(0)})} = \left\{ \frac{\omega_1(P_{12}(p), p) \omega_2(P_{11}(p), p) \left( \frac{dp}{dp_1} P_{11}(p) \right)}{\omega_1(P_{12}(p), p) \omega_1(P_{11}(p), p) \left( \frac{dp}{dp_1} P_{11}(p) \right)} \left[ \frac{dp}{dp_1} P_{12}(p) \right]^{-1} \right\}_{p=\sigma^{(i)}}.
\]
\[
(c.10)
\]

From (c.16), (c.7), (c.9) and (c.10) it results that

\[
\lim_{i \to \infty} \frac{R_2(\sigma^{(1)})}{R_2(\sigma^{(0)})} = 1 \quad \text{for} \quad w_1 > 0, \ h_1 > 0;
\]

\[
= \frac{w_{11} + w_{10} \alpha_{11} \alpha_{12}}{w_{01} + w_{10} \alpha_{12} \alpha_{11}} \quad , \quad w_{11} = 0, \ h_{11} > 0;
\]

\[
= \frac{h_{01} + h_{10} \alpha_{12} \alpha_{11}}{h_{01} + h_{10} \alpha_{11} \alpha_{12}} \quad , \quad w_{11} > 0, \ h_{11} = 0;
\]

\[
= \frac{h_{01} + h_{10} \alpha_{12} w_{01} + w_{10} \alpha_{11}}{h_{01} + h_{10} \alpha_{11} w_{01} + w_{10} \alpha_{12}} \quad , \quad w_{11} = 0, \ h_{11} = 0;
\]

\[
\lim_{i \to \infty} \frac{R_1(\tau^{(1)})}{R_1(\tau^{(0)})} = \frac{\alpha_{11}}{\alpha_{12}} \lim_{i \to \infty} \frac{\omega_2(P_{12}(\sigma^{(1)}), \sigma^{(1)}) \omega_1(P_{11}(\sigma^{(0)}), \sigma^{(0)})}{\omega_1(P_{11}(\sigma^{(1)}), \sigma^{(1)}) \omega_2(P_{12}(\sigma^{(0)}), \sigma^{(0)})} = \lim_{i \to \infty} \frac{R_2(\sigma^{(1)})}{R_2(\sigma^{(0)})},
\]
\[
(c.12)
\]

for all the four cases occurring in (c.11).

\textbf{ Remark C.1.} Note that (2.6) iv, v imply that the quotients in (c.11) are well defined. \( \square \)

For the definition of the meromorphic functions introduced in section 5 we have to investigate the existence and determination of the smallest positive integers \( m_2 \) and \( m_1 \) for which the series

\[
\sum_{i=1}^{\infty} \frac{R_2(\sigma^{(i)})}{\sigma^{(i)} m_2 + 1} \text{ and } \sum_{i=1}^{\infty} \frac{R_1(\tau^{(i)})}{\tau^{(i)} m_1 + 1},
\]
\[
(c.13)
\]

converge absolutely, cf. (5.10).

Put, cf. (c.11) and (c.12),

\[
\rho := \lim_{i \to \infty} \frac{R_2(\sigma^{(i)})}{R_2(\sigma^{(0)})} = \lim_{i \to \infty} \frac{R_1(\tau^{(i)})}{R_1(\tau^{(0)})} > 0,
\]
\[
(c.14)
\]

where the value of \( \rho \) varies with the four cases in (c.11). It follows for fixed but sufficient large \( i \) and \( k = 1, 2, \ldots, \) cf. (c.4), that
\[ \frac{R_2(\sigma^{(i-k)})}{R_2(\sigma^{(i)})} \sim \rho^k, \quad \frac{\sigma^{(i+k)}}{\sigma^{(i)}} \sim \left( \frac{\alpha_{11}}{\alpha_{12}} \right)^k. \] (c.15)

Consequently, for every integer \( n \),

\[ \frac{R_2(\sigma^{(i-k)})}{[\sigma^{(i+k)}]^{n+1}} \sim \frac{R_2(\sigma^{(i)})}{[\sigma^{(i)}]^{n+1}} \left\{ \rho \left[ \frac{\alpha_{12}}{\alpha_{11}} \right]^{n+1} \right\}, \quad k = 1, 2, \ldots . \] (c.16)

Because, cf. (2.6) ii and (a.13),

\[ 0 < \frac{\alpha_{12}}{\alpha_{11}} < 1, \]

it is seen that the first series in (c.13) converges absolutely for that value, say, \( m_2 \) of \( n = 0, 1, 2, \ldots \), which satisfies

\[ n = 0 \quad \text{if} \quad \rho \frac{\alpha_{12}}{\alpha_{11}} < 1, \] (c.17)

\[ \rho \left[ \frac{\alpha_{12}}{\alpha_{11}} \right]^n \geq 1 > \rho \left[ \frac{\alpha_{12}}{\alpha_{11}} \right]^{n+1} \]

and (c.17) implies that \( m_2 \) exists.

Analogously, it follows from (c.4) and (c.14) that \( m_1 \) is that value of \( n = 0, 1, 2, \ldots \), which satisfies (c.17) and hence it is seen that \( m_2 = m_1 \). Put

\[ m := m_1 = m_2. \] (c.18)

Because \( |a_i| \to \infty \), cf. (c.2), it follows that for fixed \( p \) and sufficiently large \( i \),

\[ 2|p| < |\sigma_i| \Rightarrow \frac{2}{3} < \left[ \frac{p}{\sigma_i} - 1 \right]^{-1} < 2. \] (c.19)

Note that for \( k = 1, 2, \ldots \),

\[ \frac{R_2(\sigma^{(i+k)})}{p - \sigma^{(i-k)}} \left[ \frac{p}{\sigma^{(i+k)}} \right]^m = p^m \left[ \frac{p}{\sigma^{(i+k)}} - 1 \right]^{-1} \frac{R_2(\sigma^{(i+k)})}{[\sigma^{(i+k)}]^{m+1}}, \] (c.20)

and hence it follows from (c.16), (c.19), (c.20) and the definition of \( m_2 \), (c.18), that the series

\[ \sum_{i=1}^{\infty} \frac{R_2(\sigma^{(i)})}{p - \sigma^{(i)}} \left[ \frac{p}{\sigma^{(i)}} \right]^m \text{ and } \sum_{i=1}^{\infty} \frac{R_1(\tau^{(i)})}{p - \tau^{(i)}} \left[ \frac{p}{\tau_i} \right]^m \] (c.21)

converge uniformly and absolutely in every circle \( |p| < R \), whenever the terms with poles inside the circle with radius \( R > 1 \) are deleted, cf. [16] chapter 7.4, [3], p. 219.

Remark C.2. It is readily seen that if in the series (c.21) the exponent \( m \) is replaced by \( m + h \), with \( h \) any positive integer, that the series so obtained also converge uniformly and absolutely in the same sense as (c.21) does, see further remark 6.3.
