A NOTE ON THE MOVABILITY OF CHAINS
The Mathematical Centre, founded the 11-th of February 1946, is a non-profit institution aiming at the promotion of pure mathematics and its applications. It is sponsored by the Netherlands Government through the Netherlands Organization for the Advancement of Pure Research (Z.W.O.), by the Municipality of Amsterdam, by the University of Amsterdam, by the Free University at Amsterdam, and by industries.
A note on the movability of chains

Prof. Dwyer posed the following question:
Is it true that, given a chain $C$, if for each $a \in C$ there is an
automorphism $\phi_a$ of $C$ (i.e. a 1-1 monotonic map of $C$ onto itself) such
that $\phi_a(a) \neq a$ then there is an automorphism $\phi$ of $C$ such that
$\forall a \in C \; \phi(a) \neq a$?
For various reasons the answer is negative, and some counterexamples
will be given here.

1. Definitions

A chain is a totally ordered set.
If $C$ is a chain and $p \in C$ then $R(p) = \{q | \phi \in \text{Aut}(C) \text{ and } \phi(p) \neq p \rightarrow \phi(q) \neq q\}$ where $\text{Aut}(C)$ is the set of automorphisms of $C$, that is,
$R(p)$ is the set of points which must move as soon as $p$ is moved.
(In particular, if $p$ is not movable $R(p) = C$).
If $\phi$ is an automorphism of $C$ and $\phi(p) \neq p$ then $\phi^P$ is the
automorphism defined as follows:

$$\phi^P(x) = \begin{cases} \phi(x) & \text{if for some } n \in \mathbb{Z} \quad \phi^{-n}(p) < x < \phi^{n}(p) \\ x & \text{otherwise} \end{cases}$$

and $I(\phi; p) = \{q \in C | \phi^p(q) \neq q\}$.
A chain $C$ is called homogeneous if $\forall a, b \in C \; \phi_{ab} \in \text{Aut}(C) : \phi_{ab}(a)=b$
and bihomogeneous if $\forall a, b, p, q \; \phi_{ab, pq} \in \text{Aut}(C) : \phi_{ab, pq}(a) = p$ and
$\phi_{ab, pq}(b) = q$.

2. Propositions

Prop 1. If $\phi(p) \neq p$ then $R(p) \subseteq I(\phi; p)$
Prop 2. $p \in R(q) \rightarrow R(p) \subseteq R(q)$
Prop 3. If $p \notin R(q)$ and $q \notin R(p)$ then $R(p) \cap R(q) = \emptyset$.
Prop 4. If $C$ is homogeneous then either $\forall a \in C \; R(p) = \{p\}$
or $C$ is the sum of a number of chains $C_\alpha$, all isomorphic,
homogeneous and without first or last point such that
$p \in C_\alpha \rightarrow R(p) = C_\alpha$. 
Proof 1. and 2. are immediate from the definitions.

3. Let $\phi_1$ be an automorphism of $C$ such that $\phi_1(p) \neq p$ and $\phi_1(q) = q$. We may suppose $p < \phi_1(p) < q$ (otherwise if $\phi_1(p) < p$ then $\phi_1^{-1}(p) > p$. $\phi_1$ maps $R(q)$ onto itself, therefore $\phi_1(p) \in R(q)$, so there exists a $\phi_2 \in \text{Aut}(C)$ such that $\phi_2 \phi_1(p) = \phi_1(p)$ and $\phi_2(q) \neq q$. We may suppose $p < \phi_1(p) < \phi_2(q) < q$. Now $\phi_2 \phi_1(p) > p$ and $\phi_2 \phi_1(q) < q$ so $I(\phi_2 \phi_1;p) \cap I(\phi_2 \phi_1;q) = \emptyset$ and because of prop 1. the proposition is proved.

4. Suppose $p < q \in R(p)$. Let $\phi(p) = q$, $\phi \in \text{Aut}(C)$, then $\phi^2(p) \in R(q) \subset R(p)$ and by induction $\phi^n(p) \in R(\phi^{n-1}(p)) \subset \ldots \subset (p) = I(\phi;p)$. Since $\{\phi^n(p)\}_{n \in \mathbb{N}}$ is cofinal with $I(\phi;p)$ it follows that for each $n \in R(\phi^n(p))$ is cofinal in $I(\phi;p)$, and hence $R(q)$ is cofinal with $R(p)$.

(i) Suppose moreover $p \notin R(q)$.

Let $\phi \in \text{Aut}(C)$ such that $\phi_1(q) > q$ and $\phi_1(p) = p$.

If $\phi_1(q) < \phi(q)$ then $\phi_1(q) \in R(q)$ so by the above reasoning $\{\phi_1^n(q)\}_{n \in \mathbb{N}}$ is cofinal with $R(q)$ and therefore for some $n \in \mathbb{N}$: $\phi_1^n(q) > \phi(q)$. So we may assume $\phi_1(q) > \phi(q)$ but in this case $\phi_1^{-1}(p) < p$ and $\phi_1^{-1}(q) > q$ which would imply $q \notin R(p)$, a contradiction.

(ii) Therefore if $q \in R(p)$ then $p \in R(q)$ and the relation $\sim$ defined by $p \sim q$ iff $p \in R(q)$ is an equivalence relation. If we call the equivalence classes $C_\alpha$, the proposition is proved.

Prop 5. If $\phi$ is an automorphism moving each point of $C$, then $C$ is the sum of a number of chains each cofinal with $\omega_0$ and coInitial with $\omega_0^*$.  

Proof The relation $\sim$ defined by $p \sim q$ iff $I(\phi;p) = I(\phi;q)$ is an equivalence relation, and the equivalence classes $I(\phi;s)$ are cofinal and coInitial with $\{\phi^n(s)\}_{n \in \mathbb{N}}$.  

Prop 6. If $C$ is bihomogeneous and the sum of a number of chains each cofinal with $\omega_0$ and coinitial with $\omega_0^*$ then there is an automorphism $\phi$ of $C$ moving each point of $C$.

Proof Let $C$ be a bihomogeneous chain, and let $\{p_n\}_{n \in \mathbb{Z}}$ be cofinal and coinitial with $C$. ($p_n < p_{n+1} \forall n \in \mathbb{Z}$)

For each $n \in \mathbb{Z}$ let $\phi_n$ be an automorphism of $C$ such that $\phi_n(p_n) = p_{n-1}$ and $\phi_n(p_{n+1}) = p_n$. Define an automorphism $\phi$ of $C$ by $\phi(x) = \phi_n(x)$ if $p_n \leq x \leq p_{n+1}$, then $\phi$ moves each point of $C$.

In the general case, paste together automorphisms of the summands to get a $\phi$ moving all of $C$.

3. Examples

1. By prop 5. it is easy to construct examples of chains in which each point can be moved by an automorphism, but in which not all points can be moved by the same automorphism; for example, the long line $(\omega_0^* + \omega_1) \times [0,1]$ ordered lexicographically is connected and bihomogeneous, but since it has no gaps with right- or left-character $\omega_0$ there cannot be an automorphism moving each of its points. Likewise $\mathbb{Z} \times (\omega_0^* + \omega_1) \times [0,1]$, ordered lexicographically is a homogeneous example which is cofinal with $\omega_0$ and coinitial with $\omega_0^*$.

2. An example with $R(x) \neq \{x\}$ for all $x$:

Let $C_0 = \mathbb{Z}$

$C_1 = (C_0 + A_1) \times \mathbb{Z}$ ordered antilexicographically (i.e. according to last difference)

$\vdots$

$C_{n+1} = (C_n + A_{n+1}) \times \mathbb{Z}$

where $\mathbb{Z} = \omega_0^* + \omega_0$ and $A_n = \omega_n + 1$; let $a_n$ be the last element of $A_n$.

Then $C_n$ can be thought of as embedded in $C_{n+1}$ by $x \in C_n \rightarrow (x,1) \in C_{n+1}$.

In this way an inductive system is obtained with inductive limit (union) $C$.

Let $x \in C$, then for some $n$ $x \in C_n$; now $\phi_n$ defined by
\[ \phi_n(z) = \begin{cases} (y, k+1) & \text{if } z = (y, k) \in C_n \\ z & \text{otherwise} \end{cases} \]

is an automorphism of C such that \( \phi_n(x) \neq x \).

Now suppose \( \phi \) is an automorphism of C such that for each \( x \in C \) \( \phi(x) \neq x \). Since \( (a_n, k) \) is the limit of an ascending sequence of type \( \omega_n \) for each \( k, n \) but no other point in the interval \([a_n, k), (a_n, k+1)\) is \( I_{n, k} \) is, it follows that \( \phi[I_{n, k}] \cap I_{n, k} = \emptyset \) (because either \( \phi((a_n, k)) \geq (a_n, k+1) \) or \( \phi((a_n, k+1)) \leq (a_n, k) \)).

(In fact this says that \( R(a_n) = C_n \).

Let \( x_0 \in C \). Then \( \exists m : x_0 \in C_m \) and \( \phi(x_0) \in C_m \).

Now look to \( C_{m+1} \). Here \( x_0 \) is called \( (x_0, 1) \) and \( \phi(x_0) \) is called \( (\phi(x_0), 1) \). Since both \( (x_0, 1) \) and \( (\phi(x_0), 1) \) lie in \( I_{m+1, 0} \), it follows that \( (\phi(x_0), 1) \in I_{m+1, 0} \) and \( \phi[I_{m+1, 0}] = \emptyset \), a contradiction.

3. The countable case

If \( C \) is countable and moreover homogeneous then either there exists a pair of neighbours in \( C \), and in that case \( C \) is a sum of copies of \( Z = \omega_0^* + \omega_0 \), or \( C \) is dense and therefore isomorphic to \( Q \).

However, a non-homogeneous example which is countable can be constructed by modifying the previous construction:

\( C_0 = Q \) and \( A_n = \{0, 1, 2, \ldots, n\} \).
